LEAVILLE. Three first-aid teams from the Yak Mining, Milling & Tunnel Co. competed for prizes on October 29. One team gave an exhibition of mine-rescue work on Labor Day, but the last results show great improvement. L. P. Shephard, safety engineer at the Arkansas Valley smelter, has returned from the fifth annual Safety Congress at Detroit, and considers that the safety-first movement is of far-reaching importance.

MONTANA

In the November issue of the *General Electric Review* most of the 130 pages are taken up by articles on electric traction, more especially with development in Montana. The use of hydro-electric power in that State is increasing rapidly, and besides being consumed by railways for ore transport and other purposes, the mining industry calls for large demands on the supply. The accompanying map shows the points of water-power development and consumption of electricity.

In the last number of the Montana Society of Engineers' quarterly journal, the present status of oil and gas prospecting in that State is discussed by D. C. Bard and Chester Steele. At present there are 12 drill-holes under way in various parts of the State. So far there is only one commercial oilfield, that near Elk Basin. Its capacity is 10,000 bbl. daily. Possibilities of finding more oil are considered good, judging by geological conditions. Gas has been found at three places, that at Havre being the best. The development of oil and gas for Montana industries is of immense importance.

BUTTE. With three shifts the Butte-Duluth plant is in operation after a year's idleness. During the testing period the

MAP OF MONTANA, SHOWING POWER-PLANTS, TRANSMISSION-LINES, RAILROADS, AND MINING CENTRES SUPPLIED BY ELECTRIC POWER.

rate of treatment is to be two tons daily. Resumption of work has stimulated the eastern part of the district.

According to H. N. Knowlton, of the Forest Products Engineering Department of the U. S. Forest Service, Butte mines are using 50% more timber than in 1911. The ratio of increase would not register the difference in mining operations accurately, as 1911 was a slack year for the mining industry of this centre, due to labor disturbances and other conditions, while 1916 is the most prosperous year in the history of Butte. The information is obtained mainly from the Anaconda, Butte & Superior, Elm Oribu, North Butte, East Butte, Davis-Daly, and a few smaller properties.

IDAHO

HAILEY. The Wilbert Gold Mining Co., operating in the Wood River district, distributes \$10,000 in dividends on November 15. This makes \$50,000 in about a year. The surplus is \$13,000. Thirty men are employed underground and in the mill.

KELLOGG. During September the Caledonia company's profit was \$100,000. On November 5 the regular monthly distribution of 3c. per share, equal to \$78,150, was paid. This makes a total of \$833,600 for the current year.

MILAN. At the American Commander claims the adit being driven has passed through several promising lead stringers.

NINE-MILE. At the Rex mine the Riblet aerial tram will be ready for carrying ore next week. Two crushers and a sorting-belt are being installed. Ore reserves are estimated at 12 to 18 months' supply for the 200-ton plant.

MICHIGAN

Houghton. At No. 1 re-grinding plant of the Calumet & Hecla, Chilean mills are to be replaced by Hardinge conical mills, one of the latter for two of the former.

MISSOURI

JOPPIN. All grades of zinc ore were stronger last week, the range being from \$67 to \$75.50 per ton. The output of the region was 9129 tons of blende, 2088 tons of calamine, and 1328 tons of lead, averaging \$68 \$19, and \$85 per ton respectively. The total value was \$833,613.

At a recent meeting of the Southwest Missouri Mine Safety and Sanitation Association, Walter Gregg gave a talk on efficiency in burning fuel, and on boiler arrangement.

The Continental Zinc Co.'s tract, operated by Frank Bryan, is producing 8 tons of first-class coal daily. The seam being mined is 4 ft. thick.

NEVADA

GOLDFIELD. Final figures of the Goldfield Consolidated for September show that 25,800 tons of ore gave a net realization of \$16,072. Costs totaled \$5.83 per ton, including 4c. for filter and 5c. for flotation royalties. Development covered 2255 ft., at a charge of \$6.83 per foot.

Good-grade ore has now been opened for a long distance in the Jumbo Junior, at a depth of 880 ft., which is regarded as of importance to this district. The Extension, Kowanas, Spearhead, and Mercer may benefit by the discovery.

PHOENIX. The new 300-ton rolling treatment plant at Pullmanville is a success, making a profit of \$5 per ton. The recovery of lead is 94%, gold 36%, and silver 30%. Weeds in the dump are troublesome, but when removed the precious metal extraction will be doubled.

ROCHESTER. The A. Leach & Sons Rope Co. of St. Louis is to construct a two-mile aerial tram to connect the Rochester Mines Co.'s mine and mill. The cost will be \$1,000,000, the work to be completed in 60 days. The cost of hauling ore will be between 6 and 9c. per ton, against 19c. at present via a haul-tramway.

(Special Correspondence.)—The Buckskin National Co. is

driving an adit to intersect the upper vein, which is 285 ft. west of the vein on which most of the work has been done, and prospects well near surface. The main orebody has been opened to a depth of 400 ft., and developed by 1300 ft. of laterals. Forrest Bell is superintendent.

The Hatch lease on Buckskin National ground is milling ore of good grade. The winze from the 300-ft. level has gained a depth of 25 ft., and at this point a cross-cut has cut the vein. Approximately 40 in. is worth \$50 per ton. A 2000-ft. adit has been started to cut the vein-system at a depth of 650 feet.

Wallace, a new camp about 10 miles south-west of Winnemucca, is claiming attention. On the Wallace & Kantenwein group two distinct veins have been uncovered, both containing gold and silver. A shaft is down 20 ft. on a 6-in. shoot of \$200 ore. Leases have been secured by Hermann & Truitt, Abel & Loinaz, E. D. Rogers, and several others. The place is five miles from Rose Creek station on the Southern Pacific.

Construction of the new aerial tram of the Rochester Mines Co., at Rochester, is proceeding. It will be over two miles long, and has a capacity of 500 tons per day. Improvements to the mill are going forward, and a Monarch furnace has been installed in the refining department. Inclement weather has somewhat hampered recent surface work. Underground operations are satisfactory, according to the report of the superintendent.

The west cross-cut from the 107-ft. level of the Nenzel Crown Point is out over 800 ft. and has cut eight shoots. A 5000-ft. three-inch pipeline is being constructed from South American canyon to furnish plenty of water. A late snow-storm delayed work several days.

Winnemucca, October 24.

NEW MEXICO

(Special Correspondence.)—The Socorro M. & M. Co. shipped 1800 lb. of gold-silver bullion from operations covering the first half of October.

Timbering of the new shaft below the 500-ft. level has been started at two different points by the Mogollon Mines Co. During the week 980 tons of ore was treated, and 1500 lb. gold-silver bullion smelted for the first half of the month.

The Oaks Company milled another lot of ore during the week, taken from development work on the Clifton mine.

A representative of the State Engineer's office has visited Mogollon, securing data and inspecting proposed hydro-electric sites. As all these power installations are under the jurisdiction of the State, this move is thought to augur favorably for an early realization of adequate and cheaper power for the district.

Mogollon, October 24.

OREGON

SUMMIT. The Taber Fraction and Rastus mining claims, comprising three acres of ground, have been sold to James A. Howard and associates of Baker, by the Taber Fraction Mines Co. for \$60,000, according to information received by A. G. Hammer of Spokane, who owned 70% of the shares. The Taber company's holdings are regarded as the richest for their size in Oregon, and in the 15 years they were operated before litigation caused suspension, about 8 years ago, they were credited with earnings of \$250,000. Work was resumed a few days ago through the workings of the E. & E. mine, adjoining, at a depth of 800 ft. vertical in Taber ground.

TEXAS

(Special Correspondence.)—The large deposit of celestite (strontium sulphate) three miles from Austin may be developed in the near future. It is owned by Judge R. C. Walker of this city. He proposes to install machinery.

Austin, October 26.

(S. P. Correspondence.)—The Texas Graphite Co. has made considerable progress in the enlargement of its mill, situated near ore. It has enough graphite developed to keep a mill of much

larger capacity than the present one in constant operation. Dan McFarland, manager, returned to the property recently from California.

Burnet, October 30.

(Special Correspondence.)—The mineral exhibit at the recent International Soil Products Exposition held here attracted much attention on the part of visitors. Collections of ore from many of the mines of the South-west and Mexico were on exhibition. One of the features of the mining department was a modern assay-office that was in actual operation by students of the Texas State School of Mines and Metallurgy. The equipment of the assay-office was of the most modern type, and was brought direct from the laboratories of the School. A large collection of ore samples, including many rare minerals, was also included in the School exhibit. F. H. Seamon, head of the chemistry department of the School, and H. D. Pallister of the geological department were in charge of the exhibit. Included in the mineral display that was made by Grant county, New Mexico, in charge of M. W. Porterfield of Silver City, were ore and water buckets of buffalo hides, used by the Spaniards in operating mines near Silver City in 1785. These ancient relics were discovered in the deepest workings of the mines of the Chino Copper Co. at Santa Rita. The buckets were used by the Spaniards when they worked the mines 131 years ago. The buckets are not of rawhide, as rawhide is known today. They are shrunken and of a greenish color from the copper ore. The hair is still on the hide. There was also shown in this exhibit a framework of timbers that was placed in the mine by the Spaniards and which is still in perfect condition. The timbers are less than four feet high, as the shafts driven by the Spaniards were only high enough to permit a man to crawl through them.

El Paso, October 30.

(Special Correspondence.)—Fire that considerably damaged the lower workings and mine equipment of the Chisos Mining Co. has delayed operations of this quicksilver property somewhat. Orders were immediately placed for new plant, which is expected to be installed in a short time. The furnace of the company was not damaged.

Terlingua, October 30.

UTAH

PARK CITY. Ten mines and lessees produced a total of 6311 tons of shipping ore and concentrate during October. The value was \$252,000. In September the quantity was 5345 tons.

TINTIC. Thirty-two companies and lessees produced 39,400 tons of ore and concentrate during October, valued at \$975,000. This was one of the heaviest months in the current year.

WASHINGTON

SPOKANE. The activities of the Anaconda Copper Mining Co. in the Coeur d'Alene district of Idaho, where it has a large zinc mine, have revived rumors that the company contemplates establishing electrolytic-zinc reduction works in or near Spokane, and it is said that representatives have been investigating the old smelter site three miles down the Spokane river with a view to purchase. Cornelius Kelly of Anaconda, vice-president of the company, with members of the metallurgical staff, were here several weeks ago investigating conditions, and they were here again recently checking their original preliminary survey of the situation.

The Loon Lake Copper Co., which owns and operates the Loon Lake property, 40 miles north of Spokane, in Stevens county, has authorized the expenditure of \$15,000 for further development, according to Frank G. Crane, secretary-treasurer, who states that the work will begin immediately. The mine is to be opened to 300 ft. greater depth, and levels will be opened each 100 ft. A 50-hp. boiler and engine, to operate the hoist and pumps, now are being installed together with a compressor and ventilating system. The lowest returns from shipments to the smelter were 11%, and the highest 13.75% copper.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

HOWARD D. SMITH is in New York.

E. M. ROGERS is here from New York.

L. D. RICKETTS was here last Saturday.

A. C. BEATTY is expected shortly in San Francisco.

F. F. SOSTWICK, of the Seoul Mining Co., is in New York.

F. L. SIZER, after a brief visit to San Francisco, has returned to Butte.

L. O. HOWARD is now in charge of the International smelter at Miami.

E. C. BLOOMFIELD has obtained a commission in the Canadian Engineers.

N. M. MUIR is superintendent of the Hanford mines at Jarbidge, Nevada.

JOHN BENDEL has been placed in charge of the power-plant at the Alaska Juneau.

ARTHUR K. ADAMS has gone to Chile as geologist to the Andes Copper Company.

H. L. CHRISTENSEN has been given general charge of mill-work at the Alaska Juneau.

H. H. COLLEY has been promoted to be superintendent of the Old Dominion mill and smelter, at Globe.

W. J. LAKELAND has resigned his position with the Burma Mines to join the Indian Army Reserve of Officers.

HENRY V. SNELL has been appointed superintendent and general manager for the Miami Consolidated Mines Co.

P. H. CRAWFORD left San Francisco for Nicaragua on November 4 to become superintendent of the Grecia mine.

W. W. WISNIOX has been appointed consulting engineer for the Big Casino Mining Co., operating near Searchlight, Nevada.

CHARLES BRUFF, of the firm of Bradley, Bruff & Labarthe, has left Juneau for Arizona, to assume charge of the construction of a large mill.

W. E. MITCHELL has gone from Anaconda to Great Falls to take charge of the Anaconda company's residue-treatment plant in the zinc department.

W. D. THORNTON succeeds THOMAS F. COLE as president of the Greene-Canaan Copper Co. It is understood that Mr. Cole is retiring gradually from active participation in mining affairs.

THOMAS RICKARD died on November 2 at Wimbledon, London, at the age of 85. He was the son of Capt. James Rickard, who came to California for John Taylor & Sons in 1850 to examine the Mariposa grant. As the senior member of the firm of Rickard Bros. he will be remembered by the older generation. A Cornishman by birth, a keen observer, a remarkable linguist, and an engineer of world-wide experience he played a leading part in the profession thirty years ago. Before practising as consulting engineer he was manager of important mining enterprises in Italy, Spain, Russia, and South Africa. The older engineers will recall his fine presence and courteous manner, as well as his wide fund of information. To them the news of his death will come like a regretful echo from days now far in the background of events. He was the last and the eldest of five brothers—William Henry, Richard, Reuben, and Alfred—all of whom played a notable part in mining, in our West as well as in other regions. He is survived by three sons, T. A., Forbes, and Herbert, and by three daughters, one of them the wife of F. W. Baker.

DAVID H. BIRDSALL, who for many years represented the Giant Powder Co. as salesman in the Pacific Coast States, died at his home in San Rafael, California, November 3, at the age of 84. He was known to nearly every miner in the country, and his many friends cannot fail to feel regret at knowledge of his death.

THE METAL MARKET

METAL PRICES

San Francisco, November 7.

Antimony, cents per pound	14.00
Electrolytic copper, cents per pound	29.25
Pig lead, cents per pound	7.25—8.50
Platinum, soft and hard metal, per ounce	100—106
Quicksilver, per flask of 75 lb.	\$80
Spelter, cents per pound	12
Tin, cents per pound	43
Zinc-dust, cents per pound	20

ORE PRICES

San Francisco, November 7.

Antimony, 50% metal, per unit	\$1.25
Chlorine, 4% and over, for cars California, per ton	15.00
Magnetite, crude, per ton	8.00
Manganese, 50% under 35% metal not desired	16.00
Tungsten, 60% W.O., per unit	17.00

New York, November 1.

Antimony: For high-class ore \$1.50 per unit has been paid, but only small quantities are available.

Molybdenum: Dealers report that the demand is steadily increasing, a part of it coming from new buyers. Contracts have been closed for all of 1917. Ferro-molybdenum has sold in the week at \$1 per lb. of molybdenum contained. The ore is nominally quoted at \$1.75 to \$1.85 per lb. for 50% molybdenum-content.

Tungsten: A good business is reported for October. Prices range for \$16 to \$17 per unit, according to quality. For some material \$15.50 has been taken. On the other hand, some interests ask \$18, but no business has been done at this figure. Practically all the tungsten ore on the here on future shipments has been sold. The foreign demand continues good.

EASTERN METAL MARKET

(By wire from New York.)

November 7. Copper is active, tending to become stronger; lead is firm, spelter is gathering strength, the demand being steady.

COPPER

Eastern Metal Market

New York, November 1.

Domestic buyers of copper have been active in the past week, and the market is extremely strong.

Zinc is higher, with producers looking for a still stronger and sustained market. Dealers are buying at the present level.

Lead is fairly steady, but dull.

Large consumers of tin have been active buyers.

Antimony is dull again.

Aluminum is a little easier.

Excited efforts on the part of consumers of pig iron to cover their future requirements, together with the high price of coke, has caused the iron market to advance by leaps and bounds. Southern No. 2 iron is held at \$17, Birmingham. Virginia No. 2X is quoted at \$20, furnace, but the leading producers are out of the market. No. 2 Northern foundry is held at \$23 at Pennsylvania and Ohio furnaces, \$24 at Chicago, and \$25 at Buffalo. Steel-making irons are correspondingly high.

The steel mills continue to turn away export business. Prices announced by the Carnegie Steel Co. and the Illinois Steel Co. are 3.25c., Pittsburg, for plates; 2.80c., Pittsburg for shapes and 2.70c., Pittsburg for bars, deliveries at the convenience of the mills. Eastern Pennsylvania mills quote higher, asking at least 4c., Pittsburg, for plates, and 2.85c., Pittsburg, for structural shapes and bars. From all directions come complaints of the car shortage; meanwhile fuel costs are advancing. Prompt foundry coke is quoted up to \$8.50 per net ton at oven; prompt furnace, up to \$7.50. Next year's price for iron ore is expected to be \$1 per ton higher.

COPPER

New England brass-mill interests did some heavy buying of electrolytic on October 30 and 31, estimates placing the amount taken at 25,000,000 lb. The report referred to a week ago, to the effect that European interests were in the market for a large tonnage—said to be 1,000,000 lb.—is still existent, but no sale has been closed. Near-by metal is scarce, and none too much first quarter is available. It is predicted that if the demand continues, the end of the year will see first-quarter metal entirely absorbed. The brass mills have been buying to cover new contracts for their products, the demand for which seems to have no limit. While the recent buying has stiffened the market it has not caused any considerable advance in actual prices, and electrolytic is still 28.50 to 29c. per lb. for reasonably prompt delivery. December is quoted at 28.25 to 28.75c., and first quarter at 27.50 to 28c. Lake copper sold this week for prompt delivery at 29c. Near-by Lake is exceedingly scarce. Hot-rolled sheet copper is quoted at 37.50c., and cold rolled at 38.50c., delivery in the case of each to be at the convenience of the mill. Copper rods are 43c. per lb. and sheet brass 42 to 46c. These prices are mentioned merely to give an idea of the costs which manufacturers using such products must meet. The October exports totaled 29,180 tons. The spot quotation for electrolytic at London yesterday was £142 10s. against £144 a week previous.

ZINC

Quotations are on the upward trend, and representatives of the producers are frank in saying they expect to see them go higher. They expect high prices in the coming winter, and their view seems to be shared by dealers, for the latter have in recent days been placing contracts for future deliveries. Not only have the dealers been purchasing, but the brass mills have been active also, and under the combined influence of buying and a seeming unwillingness on the part of some producers to part with metal, prices have advanced. The spot quotation yesterday was 10.37½c., St. Louis, and 10.62½c., New

York. A slight cold snap last week is reported to have interfered with the operation of gas-fired furnaces in the West, and production was immediately affected. One result of the incident was to start speculation as to what will happen to these furnaces when real cold weather sets in. November delivery was quoted yesterday at 10.25c., St. Louis, December at 10.12½c., and first quarter at 10c. The spot quotation at London yesterday was £52 15s., against £54 a week ago. October exports totaled 12,180 tons. This is a great showing, but not a record-breaker. Of interest to consumers of zinc is the following announcement issued by L. Vogelstein & Co., New York:

"In view of the car shortage condition existing throughout this country and the movement on the part of the various railroad companies to increase the minimum carload lot from 50,000 to 60,000 lb. for spelter, and presumably for copper and lead, we will in future make sales in 30-ton lots instead of 25 as heretofore. However, we are perfectly willing to sell you 25-ton lots with the understanding that in the event of the railroads charging any additional freight on account of our shipping less than the minimum of 60,000 lb. you will assume this extra freight. We are advising you of this change at this time because the railroads have the right to ask the Interstate Commerce Commission for permission to publish the new minimum carload rate upon giving five days' notice, and it lies within the jurisdiction of that Commission to grant such request."

The base price of sheet zinc has been advanced to 16c. f.o.b. mills, carload lots, 8% off for cash.

LEAD

Throughout the week the market has been dull, but prices are fairly firm. The A. S. & R. Co. continues to quote 7c., New York, and 6.92½c., St. Louis. Independents in the past few days have been cutting the latter price in the West, while at Eastern points they are meeting the quotation of the big producer. Most of the recent business has been in the West. The situation is strong for the reason that near-by metal is not plentiful, consumption continuing to keep pace with production. Japan was a heavy buyer about ten days ago. The exports are large, those of October amounting to 4535 tons. The London market is unchanged at £30 10s.

TIN

Tin-plate mills, having fixed their 1917 base at \$5.75 to \$6 per box, and having booked heavy contracts for next year's delivery, have been active buyers of tin in the past week. On two or three days 400 or more tons have changed hands, mostly future deliveries. Despite the activity and the fact that licenses to ship from England are not so freely granted as they were a few months ago, the price has remained fairly steady. Spot Straits was quoted yesterday at 41.87½c. Spot Banca was quoted at 41.25c. As will be noted, the difference between Straits and Banca is much less than usually prevails. The large stock of spot Banca recently on the market has been pretty well cleaned-up, but more is expected to arrive this month. Total deliveries into consumption in October totaled 4556 tons, of which 556 tons came via Pacific ports. October arrivals totaled but 2655 tons. In stocks and landing at the end of the month was 3419 tons. The quantity now afloat is 2025 tons—regarded as small.

ANTIMONY

The market is extremely dull, and spot Chinese and Japanese can easily be had at 13 to 13.50c., duty paid.

ALUMINUM

For No. 1 virgin aluminum, 98 to 99% pure the quotation is 64 to 65c. per pound.

Mining Decisions

ABANDONMENT OF A MINERAL LEASE.

Under a mining lease made in 1862 operations were conducted until 1889 at which time the lessee paid up royalties due in full, dismantled its plant and ceased operations for 20 years, neglecting however to give notice of termination in writing as required by the lease. The lessors offered no objection and thereafter one of them took possession of the land and sold stone therefrom to a railroad company. On suit brought by executors 20 years later for minimum royalties it was held that acts of the parties constituted an abandonment and no recovery could be had.

Pursell v. Reading Iron Co. (Pennsylvania), 232 Federal, 891. June 7, 1916.

DESTRUCTION OF OIL WELL—MEASURE OF DAMAGE.

Where a party under contract to drill a prospect-hole conducted operations so negligently that three steel under-reamers were dropped into the well, and permanently destroyed the possibility of drilling it farther, in a suit brought against such contractor by the owner, the measure of damages would be the amount expended by the owner in bringing the well to the point where such destruction occurred, not the value of the well from the standpoint of oil produced if it had not reached its intended depth. If the injury were maliciously done the treble damage rule might be applied.

North Haddon Oil & Gas Co. v. Skelley (Oklahoma), 158 Pacific, 1189. June 13, 1916.

OIL AND GAS LEASE—MINIMUM RENTALS.

A sale of oil and gas underlying land with the right to remove the same for a year and as much longer as oil and gas was found thereunder, and providing for minimum rentals, was held to be a lease in effect if not in form, and assignees of the original lessee would be under obligation to pay the minimum rentals to the lessor during a period of one year from date of lease. The rule would have been different had the lease been construed as a deed and the rental clause as a mere covenant running with the land. In the latter event the lessor could merely have executed a forfeiture, and would have been unable to recover against the assignee through lack of privity of contract with the assignee.

Pierce Fordyce Oil Assn. v. Woodrum (Texas), 188 Southwestern, 215. June 3, 1916.

SEVERANCE OF MINERALS—ADVERSE POSSESSION.

The possession of the surface of land by one who has by his conveyance of the mineral interest severed the latter from the surface is not such a possession of the underlying severed mineral interest as will permit the surface owner's prescriptive title to inure to the benefit of his grantee. A surface owner not in possession cannot be executing and recording a deed purporting to convey the minerals, or sever them, or interfere with an adverse possession already begun on the whole tract. But a conveyance and surrender of possession of such minerals by the person in actual possession of the land would sever the possessory right to the surface and minerals, and also prescriptive right, commencing to run against him.

Northcut v. Church (Oklahoma), 158 Southwestern, 100. August 9, 1916.

EXTRAJURISDICTIONAL RIGHTS—PROPERTY—MINERALS—DEEDS.

Where a State statute gives title to the minerals on notice, but does not extend to the title to the surface, the claim is

a penalty for failure to record, the Federal courts will not declare a forfeiture in favor of those who had actual knowledge of the unrecorded location. A prior locator, who, in his application for patent excludes area in conflict with the claim of a subsequent locator, thereby creates a presumption against himself in respect to his right to the excluded area. Evidence held to show that the two veins in conflict crossed on the dip but did not unite. Where plaintiff has brought suit for the "value of ores wrongfully taken," it will not be permitted to claim "damages for the conversion of ores" as personal property, simply because the latter form of relief would enable plaintiff to take advantage of the enormous increase in the market price of metals. Value *in situ* awarded as damages, costs of mining and marketing being subtracted on the basis of what it would cost plaintiff to mine and market. Plaintiff's claim for value not saved in mill tailing disallowed, it appearing that such value exists solely by reason of the rise in metal prices since the trespass was committed.

Clark-Montana Realty Co. v. Butte & Superior Copper Co. (Montana), 233 Federal, 547. May 29, 1916.

Book Reviews

MINING WORLD INDEX OF CURRENT LITERATURE. Vol. IX. By Geo. E. Sisley. P. 297. Index. Mining World Co., Chicago. For sale by MINING AND SCIENTIFIC PRESS. Price, \$2.

This volume is a bibliography of the world's literature on mining, metallurgy, and kindred subjects that has appeared in periodical magazines, government publications at home and abroad, professional papers, and new books, for the first half of the year 1916. A brief digest is given of all articles, giving a general idea of the subject treated in each paper. Subjects and authors have been alphabetically indexed, making it easy to find information on any subject. The increasing importance of flotation is shown by the space devoted to that subject. Much care and considerable work has been expended by the author to facilitate ready reference to all subjects pertaining to the mining profession.

ANALYSIS OF COPPER, ITS ORES AND ALLOYS. By George L. Heath. P. 292. Ill. index. McGraw-Hill Book Co., New York, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, \$3.

In this treatise the author has gone most thoroughly into his subject and presents a book which cannot fail to be of interest and value to all chemists and others whose work includes the investigation of copper ore, the products of copper furnaces and of copper refineries. That portion of the book devoted to the equipment of modern metallurgical laboratories, including the electrical machinery and apparatus employed, is comprehensive and concise. A chapter on mine sampling in its various phases is excellent, and deals with the various methods employed, in which the author properly says the method adopted must be determined by the character of the ore. The part devoted to reagents and standard solutions is important and though not unlike similar information to be found in other works on the subject of metallurgical analysis, could not be omitted from this volume. The automatic sampling of ore at suchers and in custom sampling-works is described in clear language, and keeps this important branch of the business before the student and professional worker in convenient and compact form. Methods for the determination of the metal, as well as the unusual accompaniments of copper ore, will be found to cover the subject quite thoroughly, and the character of the various alloys of copper is indispensable.

Although there is already a rather voluminous literature on the metallurgy of copper ore and products, it will be found that this present contribution will not be unwelcome to those engaged in any branch of copper mining or metallurgy.

EDITORIAL

T. A. RICKARD, Editor

SPELTER is said to be sold forward as far as the second half of next year. About 30% of the probable output for the first half of 1917 is under contract. This compares with a forward selling of 80% of the copper production, but it should suffice to cheer the zinc miner.

OATMAN has organized a Bureau of Mines, and we wish it good luck. A little boosting is not a bad thing and the co-operative spirit is always commendable. We note that the campaign of publicity is to be conducted "along conservative and authentic lines." That is wise. We expect that the Bureau will serve also as a source of useful information to those interested in this promising mining district.

HARVARD offers a prize of \$200 for the best essay on plumbing. We hope that this signifies the belated recognition of the fact that even if plumbing be not a fine art it is an essential branch of modern engineering. Modern society made a great mistake in ranking the dentist below the physician, and it is paying for its snobbishness; likewise the civilized community makes a big blunder in ranking plumbing as less scientific than mosquito-baiting, in forgetfulness of the fact that sanitation, like charity, should begin at home.

EMPLOYMENT of Austrian prisoners is helping to compensate for the loss of native labor at the Siberian mines. Thus the place of the Russians called to the front is being taken by the prisoners that they send to the rear. The Germans are removed farther east and north than the mining regions that we have in mind, namely, the Altai, Akmolinsk, and the Ural. The Austrians are paid the standard local wages and enjoy freedom to the extent of not being under military restraint. American mining engineers report that the Russians are treating their prisoners, both Austrian and German, well. It is likely that many will settle in Siberia after the War.

NOW that the election is over we shall have a chance to get information that, except for the usual proportion of inaccuracy, is not vitiated by political prejudice. Of late we have been told on the one hand that our prosperity is due entirely to the sale of munitions and on the other hand that it is entirely independent of the conditions created by the War. The detached observer is aware that neither statement is wholly true, but that the truth inclines to the former. War business was the spring that set our national industries going at

an accelerated speed; every part of the country has responded to this stimulus until our railroad traffic exceeds the supply of cars, our bank clearings exceed in volume anything previously recorded, and our foreign trade is unprecedented. The only cloud on the horizon—apart from the great darkness across the Atlantic, of which we are ever sadly conscious—is the mania of speculation that has begun to engage public attention. There lies a grave danger, particularly in mining.

AMALGAMATING plates in stamp-mills absorb gold, as is well known. The copper under the silvered surface becomes enriched by subtraction of the gold in the amalgam that in turn arrests the gold in the pulp that passes over the plates. We note that the September reports of the Alaska Mexican and Alaska Treadwell companies give the net yield obtained from the 'sweating' of the old plates in these two mills as \$26,035 and \$42,289 respectively, making \$68,324—a not inconsiderable sum. It would be interesting to ascertain the time and tonnage involved in this absorption. At the Yellow Aster mine, Kern county, California, when about 650,000 tons of ore had passed over the mill-plates, yielding approximately \$6,500,000—about \$10 per ton—the plates were 'sweated' and thoroughly cleaned, the result being a recovery of nearly \$125,000 or about 19 cents per ton of ore.

PROVIDENCE appears to favor the United States. Although we would have liked to see Mr. Hughes President, chiefly because of Mr. Wilson's lack of policy in Mexican affairs, we recognize that a change of Chief Executive during a time of crisis is dangerous and for that reason it may prove best that the President was re-elected. If now Mr. Wilson will re-organize the Cabinet, replacing one or two notoriously weak heads of department, and if he will adopt a clear policy toward Mexico, we shall feel as cheerful as the high cost of paper and potatoes will permit. Indeed, the report comes from Washington that he intends to take vigorous action. It is said that the President has undertaken to tackle the Mexican business and do something definite to restore order in that distressful country. We know that our clientele will be devoutly thankful if he does so. To the mining profession the closing of Mexico is a calamity.

COPPER production threatens to be much over-done before the War is over because the expansion is based on temporary requirements. It is reported that the existing plants for refining, having a capacity of 150 million pounds monthly, are to be enlarged to a capacity

of at least 240 million pounds, with still further additions in prospect. That indicates a production of 1,500,000 tons of refined copper by the end of 1917 or about 30% more than the whole world's production in the year preceding the War. The capacity of the principal refineries and the enlargements said to be planned are outlined as follows:

	Tons of copper per annum	
	Present	Prospective
A. S. & R.	456,000	690,000
Anaconda	330,000	360,000
Nichols	210,000	240,000
U. S. Smelting	102,000	120,000

FIRST PLACE in our 'Discussion' department this week is given to Mr. A. Stanley Elmore's reply to the comments made by us on his statement appearing in our issue of September 23. We thank Mr. Elmore for his courteous and interesting response. As to the relative knowledge of flotation obtaining on the two sides of the Atlantic, it is hardly worth while to dispute. The tonnage now being treated by the process in the United States ought to give, if it has not already given, our engineers an intimate and up-to-date acquaintance with the technology of flotation. At least we can say that more has been published on the technology of the subject in this country during the last two years than was given to the public in ten years previously by the practitioners across the water. We would like to know more about the use—"years ago"—of coal-tar and similar by-products instead of oil. If this included soluble frothing agents, as is likely, it is an important fact. Mr. Elmore scores a point in proving that Robson avoided the use of an excess of water. In regard to the statement that Mr. Frank Elmore obtained a suggestion from the remains of Robson's experimental material at the Glasdir mine, we accept Mr. Stanley Elmore's denial, but he places too much emphasis on the Robson & Crowder "machine." The supposition was not that any machine was used, but only test tubes and other simple laboratory apparatus, together with oil and pulp left behind, in such a way as to be suggestive of the kind of work that had been done by Robson. It would be worth while for Mr. Frank Elmore himself to publish an explicit denial and so kill the story conclusively. As to the air, Mr. Elmore ignores the discussion on Mr. Rolker's paper before the Institution of Mining and Metallurgy in 1900. The knowledge of the important part played by air came soon afterward we are ready to believe, but it was absent at the time when Messrs. Elmore, Rolker, Bayan, and McDermott discussed the Glasdir bulk oil operations before the Institution. Mr. Elmore's statement that air is "not essential to the selective action of oil in a large quantity of water" is most interesting and we direct the attention of other investigators to this assertion. The hint that the "man contest" is to arise over issues not involved in the Miami suit is highly important. We share the opinion that the Elmore vacuum patents will prove an obstacle to the monopoly of flotation by Minerals Separation. That issue has yet to be tried.

ABANDONMENT of the gold standard in Europe, or a suspension of specie payment, has been made the subject of a questionnaire by *The Analyst*. It is interesting to note that out of 92 prominent economists 82 voted that the gold standard would be maintained after the War and only 7 voted to the contrary. Mr. Adolf C. Miller of the Federal Reserve Board, and formerly Professor of Economics in the University of California, believes that the gold standard will survive, despite the fact that all the belligerent countries except England have long since suspended specie payment, and even in England it is not patriotic to ask for gold at the bank. Neither England nor Germany can hope to recover her foreign trade without a sound system of banking and finance. The German mark must be brought back to a parity with gold and the British pound sterling must recover its high prestige. No effort therefore will be spared to build up the gold supplies "so as to bring them more nearly into equilibrium with their credit currency," as Mr. Miller says. Meanwhile the world's entire supply of gold (not including jewelry or works of art) is estimated at about eight billion dollars, or as much as would make only a 60-ft. cube of metal. On that the super-structure of the world's credit is imposed. Mr. Theodore H. Price estimates that the United States holds 2½ billions of the gold of the world, or nearly as much as all the Allies, among whom Great Britain holds about one billion of gold. Germany is credited with \$600,000,000. The debts of the belligerent nations amount to 66 billions, of which 44 are debited to the Allies. The balance of trade in favor of the United States will be 2½ billions during the current year, and if the War lasts through 1917 and the balance of trade is as great as in 1916, the United States may find herself in possession of half the world's gold supply. Meanwhile Great Britain controls two-thirds of the world's gold production and there remains the possibility of so taxing jewelry and works of art as to bring a big stock of gold into the melting-pot. These last two factors have been overlooked in recent discussions. The world produces about \$460,000,000 in gold annually, of which \$300,000,000 is produced in the British dominions. The amount of gold consumed in the arts has been variously estimated; it is equal to about one half that used for monetary purposes. The moral is that we should bestir ourselves to stimulate gold mining in this country.

The Holmes Memorial

In a recent issue we referred to an association formed at Washington to perpetuate the memory and good work of Joseph A. Holmes. During the past week Dr. David T. Day, the honorary secretary of the Association, has been in San Francisco and has taken steps to arouse the interest of the mining profession in the plan to memorialize the first Director of the U. S. Bureau of Mines. Our readers will sympathize with any effort to do honor to Holmes as they were always glad to support him when alive, yet we venture to say that the most fitting

memorial to him is the complete success of the Bureau of Mines, which he organized and directed in its beginning; and if that be not enough, there is also the fact that among those now prominent in asking the public to honor him are several that tried to prevent the formation of the Bureau and the subsequent appointment of Holmes to the directorship. We say this in no mean spirit, but in justice to the memory of a good citizen. 'Safety first' was the slogan of Holmes; it has given an impulse to a great variety of systematic effort designed to decrease the risk incurred in the work of mining. It is proposed now to do something further in this direction in order to honor Holmes. The distribution of medals has been suggested as a method for recognizing the observance of safety principles. Arrangements for talks on the subject to the mine-workers might be another effective way of encouraging interest in the matter. Unfortunately, from the 'safety' point of view, the miner is essentially a venturesome man; his choice of an occupation indicates the willingness to take chances—therefore it has proved difficult to eradicate carelessness. Men will persist in entering a powder-magazine while smoking a pipe; they will insist in lowering men in a cage with the brake only; they will work under bad ground. The temperament of those that go down the mine in skips and follow a dangerous occupation amid the darkness underground will have to be changed before we make them murmur to themselves 'safety first.' One way to do it is to get some of the more thoughtful among them to give talks on the subject to their fellows: a kind of lecture from a working-man to his mates. Some of the older and better educated might be selected by the Holmes Association and paid reasonably for their work as exponents of the safety idea. We suggest this as one method of honoring the founder of the Bureau of Mines. The local branches of the mining engineering societies will be asked to give their support.

Pan-Americanism—A Myth

In the latest issue of *The Annalist*, Mr. H. J. Davenport, Professor of Economics in Cornell University, argues that there is no hope for the appreciable extension of American trade into South American markets. This opinion runs directly counter to the vigorous propaganda of the National City Bank of New York, which has been doing earnest work in a systematic effort to awaken American interest in South American trade. Professor Davenport asserts that any ground gained during the War cannot be held permanently; the reason why formerly we have not sold our products in South America being exactly the reason why in the future we shall fail to do so: we do not produce the things that the South Americans want and we do not want the things they produce. On the other hand, the South Americans do produce what Europe wants and Europe can supply them with what is wanted in South America. The things that we want to buy, Europe, not South America, is

willing to sell; what we want to sell, Europe, not South America, is able to buy. The exports of South America, like our own exports, rightly go across the Atlantic to Europe. Therefore, South America is our competitor, not our customer.

So little in the way of enlightened effort has been done to develop those new avenues of trade which the United States must find if she is to hold her present status as a creditor country that we are loth to depreciate or deprecate the work done by the National City Bank and their friends. Yet we had come to the same conclusion as Professor Davenport before we had read his article. In trying to develop trade with the countries of South America we are 'barking up the wrong tree.' We have been led by the lure of Pan-Americanism, which, like the Monroe doctrine, is a devitalized formula. The term 'Pan-Americanism' has bemused us; we have been attracted by the word 'American,' just as we were fascinated by the word 'republic' when used to designate the military autoeracies to the south of us. We have been hypnotized by a fallacy and misled by a phonograph—Mr. John Barrett.

A few days ago we listened to a paper on this subject by Mr. Lincoln Hutchinson, Professor of Commerce in the Department of Economics of the University of California. It is gratifying to know that there is a chair of Commerce in our State university and that the geographic phase of commercial activity is being elucidated for the benefit of our young men. Professor Hutchinson has returned recently from a journey of observation in South America and speaks with first-hand knowledge. He is entirely in agreement with the gentleman at Cornell, and what is equally important, with the more thoughtful and frank among South American observers. Turning to simple matters of geography, Professor Hutchinson suggests that most of our people are unaware of the fact that the whole of South America is nearer to Europe than it is to the United States. Even with the advantage of the Panama Canal, two-thirds of the area and two-thirds of the people of South America lie nearer to Europe than to us. The A. B. C. countries—Argentina, Brazil, and Chile—to which we have turned for advice on the Mexican muddle, are among the farthest from us and from Mexico. We hear occasionally of the "vast populations" of South America, but the whole area has only 70,000,000 inhabitants, while Europe, which is nearer, has six times the number of people, and the eastern part of Asia, which is no farther from us, has a population nearly ten times as great as the whole of South America. Of our trade, 50% of the imports comes from Europe and 61% of the exports goes thither, in normal times. With England, Germany, and France we do 35% of our import trade and 48% of our export trade. Only 12% of our foreign purchases come from South America and only 5% of our exports are sent thither. The sentimental notion that we are racially akin to the people south of us is a pathetic fallacy. By the last census the population of the United States was shown to be 89%

'white,' or of European origin. In so-called Latin America only two countries, Argentina and Uruguay, show any similar proportion. In Chile the whites and creoles represent 30 to 40% of the inhabitants. In all the others the Indians, negroes, and half-breeds predominate. Bolivia has only 13% 'white' population; Brazil and Peru, each 14%; Ecuador, Colombia, and Venezuela, 1 to 2%. In all of these countries the 'white' blood has been drawn from Southern Europe and not from the countries that gave us the citizens who have played the chief part in the development of our institutions and the exploration of our resources. In no South American country do our own people constitute even a significant fraction of the population. In every one of the South American countries the prevailing religion is Roman Catholic. Whether that be an advantage or a disadvantage does not arise in this argument, which has been started to prove unlikeliness between the United States and South America. Nominally the Pan-American countries are 'republics.' In theory, that is so; in practice, the reins of government are in the hands of a dictator or of a coterie of politicians, usually sustained by force of arms. 'Popular government' and 'democratic principles' are empty phrases as applied to South America, and every intelligent student knows it. Their legal system is based on the Civil Law; ours is based on the Common Law; and the divergence between the two is not easy to reconcile. The social customs of the two geographic divisions are sufficiently different to be a hindrance to a mutual good understanding. Concerning customs, as concerning humor, it is unwise to dispute. Whether administrative methods are more corrupt there than here, we do not undertake to say, but we emphasize the fact that the methods differ to the point of incompatibility. As to education, 24% of the population of the United States attends school; the highest percentage of schooling in South America is 11 in Uruguay and the lowest is 1% in Venezuela. In Chile the percentage is 9; in Argentina, 7.1; in Brazil, 3; in Bolivia, 2 only.

All of these facts are recited not in any spirit of antagonism but simply to bring home the truth that Pan-Americanism is a figure of speech, a snare and a delusion to anybody wishing to see things straight. The United States has, we believe, so many—i. e., geographic, racial, political, legal, social, educational, and commercial with Europe, particularly Western Europe, especially with England and Germany—that this attempt to steer us from our natural course should be opposed frankly and vigorously. As Professor Hutchinson has said: "We are turning from our real associates in the international world, those that have done things in the cause of free and enlightened institutions, we are assuming naively that somehow we of America, North and South, are better than those of Europe, we are playing at international politics with the kindergarten people to the south of us like a Peter Pan among the nations who has declined to grow up, we have even thought so little of the sanctity of our political ideals as to ask six of these countries to help us make up our minds as to what

our duty is in an important international question in which they have no interest whatever and in which Europe has interests second only to our own." To this we may append an expression of opinion by a distinguished Brazilian, Dr. Oliveira Lima. Writing in the *Revista do Brazil* recently, he said: "Pan-Americanism, to us, seems mockery, and impossible of realization. There is no racial, linguistic, traditional, or religious community between Anglo-Saxon America and Latin America. The geographic situation has no significance when one considers the distances separating North America from South America. * * * True, we have some interests and sentiments in common, which, properly agitated and played upon, may bring excellent results. 'Pan-Americanism' continues to represent the ideal of a single union, and, like other 'isms, is continually exhibited for the 'grand effect' on the people, but its actual influence is somewhat less than that of a substantial, solid, silver dollar." We are misled by 'isms into giving aid to 'istas, in Mexico.

Commerce finds the cheapest market as surely as water runs down-hill. Our trade before the War was mainly with Europe; and with Europe we shall have to trade, if we desire to trade profitably, when the War is over. Instead of harboring illusions concerning the possibilities of developing a big business in South America, we ought to send a commission of experts to Europe to ascertain the kinds of commodities that will be in greatest demand when peace is restored, and we ought also to give thought to creating a shipping that will carry our products overseas, instead of depending for transport upon foreign ships. During the last two years several economists and statesmen have adverted to the fact that American trade floats on British bottoms no less than the Monroe doctrine floats on the British navy, and has done so ever since Canning suggested that policy to Monroe in 1823, as a defensive measure against the Holy Alliance. With the War has come a great increase of financial responsibility and luckily we had the Federal Reserve system of banks to meet the contingency, but with Peace will come fresh duties, national and international. Is the United States to be another Korea, a hermit kingdom, that avoids dealings abroad and refuses to protect its citizens when they go away from home in quest of business or speculation? If we are to play a manly part in the comity of nations we shall want a shipping of our own to bear our products overseas and a navy adequate to guard our mercantile marine as well as our shores in the days of larger international life that loom ahead. To get the right aspect, let us rid ourselves of the hypnotic influence of mere names; let us aim to deal with people that have something to exchange, realizing that business is not built on shibboleths but on mutual necessities and the goodwill that follows the adjustment of them. Let us face east, not south, for there are the countries of our earliest origin and the markets by which our trade has been developed; there lies the past of our history and the future of our commerce.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Elmore and Flotation

The Editor:

Sir—I have just received a copy of your issue of September 23, and have read with great interest the editorial article on my notes which you have favored me by publishing.

I am under obligation to you for your sympathetic appreciation of the work of my brother and myself, and in so far as your comments are a criticism or express doubts, I recognize their friendly tone, the independent fair-mindedness, and the desire to get at the truth which prompted them. I also avail myself of this opportunity of thanking the large number of engineers who have written me; all expressing gratifying concurrence in the views expressed in my notes, and conveying their congratulations on the clear statement of the case presented.

As, in addition to answering the specific questions you put to me, I wish to make a few observations on some of your editorial comments, perhaps it will be more convenient if I take them seriatim.

You say "the flotation vendetta is better understood in London than the technology of the process." You are probably right as to the first part of this statement, but I cannot accept the latter part of it. I do not, of course, deny—it would be ridiculous to do so—the great application of the flotation process in the United States (although rather late in the day), the large amount of excellent scientific and practical work which has already been accomplished by American engineers, and the great experience they have gained. But I do say that had the work of English engineers having special experience in this branch of metallurgy been more fully drawn upon, the industry in America might have been saved a vast amount of time and money. This I am convinced of, as a result of the perusal of patent specifications filed and literature published of recent years, and of personal contact with a number of American engineers.

Almost every day I read or hear of some supposed new invention or development in connection with flotation which is announced with all the pomp and circumstance of a great discovery, but which, in fact, is "old as the hills" and quite often found to be described in some of our earlier patents or documents; to have been thoroughly tried in our testing works; proved useless for practical purposes and abandoned, or on the other hand considered part of our original invention and given to the world without rushing off to the Patent-Office to

seek further protection. Two instances come to mind as I write: first, I am told that someone has discovered that coal-tar can be used in place of oil and that this discovery constitutes a great advance. Years ago we used, for the same purpose, coal-tar, wood-tar, tar from blast-furnaces, and tar from the scrubbers of suction-gas engines. This information was spread broadcast from our testing works and was published (without being claimed) in some of our earlier patent specifications. Second, there is the case of the supposed recent discovery that gold ores can be successfully treated by the flotation process. In the year 1902 a working Elmore plant was erected on a gold mine in Australia; subsequent to that date Wernher, Beit & Co., by their engineers, made a careful investigation on a working scale of the Elmore process to ascertain its applicability to the gold ores of the Rand; furthermore, working plants were erected on five different gold mines in various parts of the world. In some cases the process was used in conjunction with cyanidation.

I now turn to the story of the virgins, quoted from Herodotus 194 in Melpomene IV. If this is, as you say, apocryphal it only emphasizes my protest against its being introduced, as it was in fact, to the attention of the Courts.

I see that you regard as new my "argument" that Robson & Crowder "avoided the use of an excess of water." As I attach much importance to this, may I say that it is not simply an "argument" but a *fact* stated in their own specifications as the following extract from British patent No. 427 of 1894 (lines 15 to 19, page 4) granted to Robson & Crowder proves:

"* * * according to this invention we effect the separation of the metallic matter by the mixture of oils alone, using such mixture to wash out the metallic matter and avoiding as far as possible the presence of water in excess of the quantity hereinbefore mentioned, as we find an excess of water prevents the successful carrying out of the invention."

To find out what "the quantity hereinbefore mentioned" is, one must refer back to line 43 on page 2 of the specification, which says:

"Thus the said substances" (crushed ore, tailings, etc.) in a *moist state*, that is to say, containing 25 to 30% of water—are to be mixed with the mixture of oils so that the metallic matter shall be removed from the "mud or mass."

That is clear enough, and further confirmation is found in Robson & Crowder's British patent No. 2538 of 1895, wherein they state that it has been discovered since

the date of their patent of the year before, that in some cases the moistening with water is fatal to good work and (at line 21 of page 2):

"It is necessary to first moisten the metalliferous substances with a liquid other than water, as, owing to some peculiar nature of the said substances (crushed ore, etc.), the water, if added first, prevents the fatty oil or matter from acting in the desired manner."

All through these two specifications it is impressed on the reader that the condition of the material operated upon must be "moist or plastic," "moist or pasty," "in a plastic condition," "a plastic mass," and that very little, if any, water is to be used.

I say that that is the absolute antithesis of what Frank Elmore did, or what he taught, and of what everyone since the publication of his work has done.

Frank Elmore's discovery was the "freely flowing pulp," the "perfectly mobile medium," into which to introduce the oil; the "crushed ore freely suspended in a large quantity of water"; the "oiling in diffuse suspension of the metallic as distinguished from the rocky particles," and all this was clearly stated in the claims of his British and German patents quoted in my previous communication.

Now to turn to your statement that I have not explained "that the plant in which his (Frank Elmore's) first experiments were made was the one at the Glasdir mine in which Robson had made his ineffective attempt." You ask me to "clear this part of the history" because you "have been informed on good authority that Mr. Frank Elmore found the remains of Robson's experimentation in the form of oil, pulp, and apparatus, at the Glasdir mine, when he himself first arrived there." On the assumption that your "authority" is as accurate as he is "good," you hint at the natural suggestion that these circumstances led Frank Elmore to experiment with Robson's apparatus. I have repeated what you have said so that there may be no misunderstanding as to what I am replying to, and so that the question and answer may be before the reader at the same time.

My reply to the above is that there is not a word of truth in it, not a shadow of justification for any one of the suggestions or innuendoes or whatever they may be. It is absolutely untrue to say that Frank Elmore ever experimented with the small Robson & Crowder machine which at one time was at the Glasdir mine (the mine referred to in my previous article); it is untrue to say that that machine was at the mine when Frank Elmore first arrived there, or that there was any of the pulp, oil, or apparatus of Robson and Crowder there. When Frank Elmore first arrived on the mine not a vestige of any of these things was present. Even the tumbledown shed in which the Robson & Crowder experiments had been made had disappeared and had long previously been replaced by a large mill containing jigs, shaking tables, crushing and classifying machinery upon the tailfines from which Frank Elmore first experimented in new apparatus constructed entirely by ourselves and at our own cost.

I am speaking from memory, but am sure I am within

the mark when I say that it was at least 12 months (and I have practically no hesitation in saying two years) after the erection of this jig-mill, and the consequent disappearance of the Robson & Crowder apparatus, that Frank Elmore first came on the property to experiment. As a matter of fact, *Frank Elmore has not at any time even seen a Robson & Crowder machine.*

Many insidious statements, with as little foundation of truth as the above, have from time to time been assiduously circulated in the hope that they would get in their deadly work before I had a chance of "nailing them to the counter," and I thank you for having drawn my attention to this one, which is new to me.

You may be interested to know that I have, somewhere among my papers, a letter from Crowder in which he congratulates us upon the success we have made where he and Robson had only encountered failure; and in which he compliments us on having discovered the one thing essential to success which had always eluded them.

I now come to your statement that "in his (Frank Elmore's) first invention he missed the third essential, one as important as the water and possibly more important than the oil—namely, air." Permit me to say you have quite overlooked the reference in my article to the important part played by air, as you will see on reference to the second paragraph of the second column on page 452 in your issue of September 23. We were quite cognizant of the fact that it was the air entrapped in the bulk of oil which rendered it capable of carrying more than its theoretical load of concentrates, even in the "bulk-oil" modification of our process.

In Frank Elmore's first patent specification the fact that the oil is impregnated with air-bubbles is stated in specific terms. I could multiply instances showing where in the very early days recognition of the effect of air or gas was quite obvious, but perhaps one more reference will be sufficient; it is to be found in a report addressed to John Ballot by Sulman & Picard, who at the time (May 1902) were engaged at the Elmore works supervising tests on gold ore from the Lake View mine. In that report the fact that the oil is "honeycombed by air" is noted. But long before that date, from the date of the earlier trials of the Elmore plant at the Glasdir mine, air was deliberately introduced for the purpose of buoying up individual greased particles of mineral and groups of greased particles, forming nothing more nor less than a "froth." This early knowledge of the effect of air was applied in two different ways, was in constant use, and was inspected in operation by a large number of engineers who visited the plant from time to time.

In the working of the Elmore plant it was found that depending upon the kind and quantity of oil used and upon other conditions there was a greater or smaller quantity of greased mineral particles which had not been collected in the bulk of the oil used, some of which were floating, some sunken, and others in an indeterminate state—suspended in the tailing-water.

With the object of recovering these greased particles, the tailing pulp was caused to travel down long launders

and over a fan-shaped distributor discharging into a spitzkasten, which resulted in the mixing of air with the pulp and caused the greased particles to float. The spitzkasten was fitted with a skimming device which removed the floating 'scum' or 'froth,' or whatever you like to call it, from the water-surface of the spitzkasten. This gave such satisfactory results that it was thought advisable to try to carry the flotation effect of air still further. So, to obtain the admixture of a greater quantity of air and secure a more certain contact of air with the greased mineral, the outlet from the spitzkasten above referred to was run into another spitzkasten where the pulp was violently agitated by fine jets of compressed air blown into the bottom of the pointed tank and the floating froth of greased mineral and air removed from the surface.

While I trust this statement will remove any doubt existing in your mind on this subject, I would like to point out as a matter that may interest other investigators that the presence of air is *not* essential to the operation of the selective action of oil in a large quantity of water. Mineral may be selectively coated with oil in the entire absence of air and this fact may give food for thought to some of those gentlemen who are rather hasty in rushing into print with theories.

With regard to the statement by Walter McDermott in his article in the *Engineering & Mining Journal* of February 14, 1903, that "the agitation with the pulp results in the oil taking up an appreciable quantity of air," I would say, with his approval, that he was not claiming then to make any new statement; he was merely stating what he knew as a result of his intimate knowledge of the regular working of the Elmore process; knowledge common to the large number of engineers who, prior to that date, had had opportunities of studying the plant in operation.

As I have shown above, we were well acquainted with the action of air in these processes right away back to the earliest days.

As I have already written more than I had intended, I do not propose to go into the question of how much or how little Froment's work aided in the development of the industry. Much of an illuminating character could be written on this point, but in the meantime I will content myself by repeating that although Froment's patent was set up as anticipation of Elmore's vacuum patent, this case was not proceeded with, and a clear defence is furnished by Stanley Elmore's 'acidulation patent' and by prior public use, as explained in my article.

As to that "keen sense of betrayal" which you think my previous article shows, and as to the resignation of my brother and myself from the Institution of Mining and Metallurgy, I would prefer to say nothing at all, as to do so would be to invite discussion along purely personal and sentimental lines, leading to no useful end.

It remains to be seen if you are correct in your statement that "the main contest over the patents is now in progress in the United States, as our readers are aware, by means of the suits brought by Minerals Separation

against James M. Hyde and the Miami Copper company respectively." Personally I do not think you are right, for I believe the "main contest" has yet to be started.

A. STANLEY ELMORE.

London, October 21.

Local Stories About Mines

The Editor:

Sir—I recall a condition at a well-known Western mine a few years ago that not only emphasizes the importance of accurate maps and records of mine-openings but tends to prove that "men willingly believe what they wish."

The mine was equipped with a drainage adit at the 1200-ft. level, and levels at 1400, 1500, and 1600 ft. The last connected, through a short raise, with a drift of an adjoining mine that served, at one time, as a means of drainage below the tunnel; but because differences arose between the respective managements, a concrete bulkhead prevented proper drainage. Except during the summer thaws when the 1500-ft. level was also flooded, the water-level in the shaft stood between the 1500 and 1600-ft. levels, the head being sufficient, apparently, to force the water through the fissure into the neighboring mine. This condition had existed about ten years.

The pressing need was for more ore. The only map of the flooded workings was an inaccurate tracing. Persistent reports were heard from offices of the company, and others, of high-grade ore on the 1600-ft. level that, it was said, was similar to ore being mined from the same vein above the 1200-ft. level. It was stated that shortly after ore was discovered on the 1600-ft. level, water broke into the drift in such volume that the miners had time only to save themselves, and that tools, machines, cars, etc., were abandoned. The water story was plausible. It was said that the local post-master, an old-time miner, was driving the drift when ore was disclosed; he was visited and questioned; he seemed reliable and to remember details clearly, the position of the ore, its appearance and approximate thickness, the inrush of water and two cars of first-class ore left on the station. The mill-superintendent, a resident of over thirty years, and a man of unquestioned veracity, stated he did not see the ore, but its existence and the miners' hasty exit were well-known facts. The various reports agreed fairly well.

It was determined to unwater the shaft, which, considering means at hand, seemed difficult; however, it was accomplished in due time and when the water-level finally stood below the 1600, the superintendent, eager to see the ore, waded with hip-boots through two or three feet of accumulated slime for several hundred feet to the breast, only to be disappointed. It was a fairy-tale. After cleaning out the 'muck,' not only was there no ore, but no tool, no piece of a machine, no car could be found on the level.

Later, a prominent man, at one time manager of the

mine, told the company's president that the ore was in a cross-cut south of the shaft, or on the side opposite to the main vein, and 35 ft. below the 1600 station. This was given little credence because knowledge of the geology indicated this cross-cut to be in foot-wall quartzite and to cut no veins of size. Nevertheless the 50 ft. of dump was cleared of years of accumulated debris, only to find the cross-cut barren.

The mill-superintendent was incredulous and had to be taken underground to be 'shown.'

Porphyry Copper

The Editor:

Sir—The interest of many mining engineers, geologists, and others is now centred in copper. This fact induces me to suggest that the present is an opportune time to correct an error in our copper nomenclature. I refer to the use of the word 'porphyry' as applied to certain deposits of disseminated copper ore occurring usually in masses of igneous rock.

The word 'porphyry' has a particular place in our scientific language. It has been used in a definite sense for many years to designate the texture of certain igneous rocks in which megaseopic crystals or grains of one mineral occur scattered through a groundmass of the same or other minerals. The appearance of such ores being similar to that of true porphyritic rock many writers adopted the expedient of using the term to define the ores. In the beginning it was used apologetically and with quotation marks. Later the quotation marks were dropped and the ores referred to as the "so-called porphyry coppers."

If these ores were always mentioned as being of porphyritic texture there would be less objection to the use of the adopted term, but since other types of copper ore are found in many districts associated with porphyritic rocks a certain amount of confusion frequently results. I have been particularly impressed with the necessity of having a better definitive for these ores since reading the paper on the geology of the Warren mining district presented by Messrs. Bonillas, Tenney, and Fauchere at the recent meeting of the A. I. M. E. and published in the September bulletin of the Institute. The authors of this splendid paper discuss several types of ore that occur in the district, among them those which are found in a porphyritic igneous rock and to which they refer as "porphyry ores;" also those which are found disseminated in limestone and which they call ores of "porphyritic texture." A careful distinction between noun and adjective and a judicious use of quotation marks has enabled them to convey definite ideas. In a less carefully written paper confusion of ideas would certainly have resulted. Readers of mining literature will recall many recent instances of confusion and ambiguity.

In view of these facts I would like to submit the following questions to those who may be interested: Would it not be well to adopt another adjective to designate this

particular type of disseminated ore? Would not the word 'interstitial' meet the requirements of the case? In my opinion this word is equally as descriptive of the physical characteristics of the ore as 'porphyry,' and less objectionable.

W. N. THAYER.

Cincinnati, October 26.

Amortization of Mine-Capital

The Editor:

Sir—Referring to the article on 'Amortization and Depreciation' by Robert S. Lewis, in your issue of September 23. There is no doubt that it would be difficult, if not impossible, for a gold-mining company to plan a definite policy for the amortization of its capital. And it is safe to say that the average stockholder would prefer to do his own re-investing. If a company is formed to conduct a mining business and I acquire stock in that enterprise, as a mining venture, I question the right of my directors to re-invest my profits for me. On the other hand, the creation of a sinking-fund (out of profits) to provide for the purchase of other mining property, when a sufficient sum has been accumulated and a desirable property found, is a different matter from putting the profits into other enterprises with the intention of making a permanent investment. It is not a great stretch of the executive's prerogative from directing the method of exploitation of the parent property to acquiring other properties of the same nature.

It may be interesting to recall that an English company, formerly operating in California, successfully carried out this plan. As far back as forty years ago the Sierra Buttes Gold Mining Co. created a reserve-fund that was allowed to accumulate until such time as the directorate thought there was a favorable opportunity to put it into a new mining enterprise. Eventually, when the original properties were almost worked-out, the management bought a new mine with the funds saved for that purpose. Fortunately the new property thus acquired afforded an excellent use for the stockholders' money. Through it the directors were enabled to continue dividends for a number of years, and the life of the company was thereby prolonged in the business for which it was chartered.

San Francisco, November 2.

JOS. C. HOPPER.

SHEET mica finds its greatest use in the electrical industry, when an insulating, non-inflammable material is necessary. It is used in sheets and as washers and discs in dynamo-electric machinery, electric-light sockets, spark plugs, insulators, in rheostats, fuse-boxes and telephones. Flexible cloth and tape, covered with mica, find varied uses in electrical apparatus. It is necessary where an insulating medium is needed and where glass would be broken.

ORE MINED in British Columbia in 1915 was 2,690,110 tons, showing an increase from that of the previous year of 511,139 tons.

Engineers for the Officers' Reserve Corps

By A. H. Babcock

The great struggle in Europe emphasizes the lack of officers available for the augmented English Army, and therefore conveys a solemn warning to the American people: the English Army and the United States Army being based on much the same organization, namely, a skeleton in peace times, to be increased as may be required in war time.

"The almost studied indifference of the American people toward reasonable preparation for the contingency of war makes more urgent the duty of all officers or those who hope to become officers, to do all in their power in advance to prepare themselves and those committed to their care for the immense responsibilities that will rest upon them when the storm bursts upon the nation.

"The trend of history shows in general a progressive decrease in the length of wars due to the enormous massing of men now possible, and the increasing power of destruction of modern weapons. The decision, in short, is sooner reached. This being the case there is more than ever before a need for adequate preparation in advance of the outbreak of war. The unprepared people or government who now-a-days find themselves on the brink of hostilities with a nation that is trained for the struggle, must expect inevitably to pay a severe national penalty.

"The preparation of a nation for war is of two kinds: one of material things, the construction of forts, arsenals, fabrication of weapons, munitions, etc., the other the training of its people. And the second is more important than the first, though in the United States the estimate of their relative importance is reversed. The people of the United States are willing to vote immense sums for preparations that concern material, but they grudge time or thought devoted to the war training of the fighting unit—the man."*

On the third of June, 1916, Congress passed an Act "for making further and more effectual provisions for the National Defense." Regulations prescribed by the President to carry this into effect have been published by the War Department, General Orders No. 32, from which the following is largely abstracted. The Officers' Reserve Corps has been created for the purpose of securing a reserve of trained men available for service as temporary officers in the Regular Army. A member of this Officers' Reserve Corps will not ordinarily be subject to call for service in time of peace. It is expected, however, that reserve officers will be ordered to duty with the troops or at field exercises or for instruction for periods not to exceed 15 days in any one calendar year, and while so serving they will receive the pay and allowances of their respective grades in the Regular Army.

The act authorizes the President "to appoint and commission as Reserve Officers in the various sections of the Officers' Reserve Corps, in all grades up to and including that of Major, such citizens as, upon examination prescribed by the President, shall be found physically, mentally, and morally qualified to hold such commissions." The age-limits fixed for appointment and re-appointment are, for a Second Lieutenant, 32 years; a First Lieutenant, 36 years; a Captain, 40 years; a Major, 45 years. These age-limits shall not apply to the appointment or re-appointment of officers in the Quartermaster, Engineer, Ordnance, Signal, Judge Advocate, and Medical sections of the Reserve Corps.

Commissions will be issued for periods of five years; and when an officer of the Reserve Corps shall reach the age-limit fixed for appointment or re-appointment in the grade in which he is commissioned, he shall be honorably discharged from the service of the United States (unless re-commissioned in a higher grade).

In time of actual or threatened hostilities, the President may order officers of the Reserve Corps to temporary duty with the Regular Army, in grades thereof which cannot for the time being be filled by promotion; or as officers in volunteer or other organizations that may be authorized by law; or in such other duty as the President may prescribe; for example, the recruit, rendezvous, and supply depots. While on such service the reserve officers, by virtue of their commissions as such, will exercise command appropriate to their grade and rank in the organizations to which they may be assigned, and shall be entitled to the pay and allowances of the corresponding grades in the Regular Army, with such increases of pay as are allowed by law for officers of the Regular Army; and they may be promoted, in accordance with their rank, to vacancies in volunteer organizations or to temporary vacancies in the Regular Army thereafter occurring in the organization in which they shall be so serving, but they shall not be entitled to retirement or to retired pay and shall be entitled to pension only for disability incurred in the line of duty and while in active service.

The Sections of the Officers' Reserve Corps shall be designated as follows:

1. Infantry Officers' Reserve Corps.
2. Cavalry Officers' Reserve Corps.
3. Field Artillery Officers' Reserve Corps.
4. Coast Artillery Officers' Reserve Corps.
5. Medical (to include the reserve officers of the Medical Corps, Dental Corps, and Veterinary Corps) Officers' Reserve Corps.
6. Adjutant General's Officers' Reserve Corps.
7. Judge Advocate General's Officers' Reserve Corps.

*"Technique of Modern Tactics," Bond & McDonough.

8. Inspector General's Officers Reserve Corps.
9. Quartermaster Officers' Reserve Corps.
10. Engineer Officers Reserve Corps.
11. Ordnance Officers' Reserve Corps.
12. Signal Officers' Reserve Corps."

Every applicant will be subjected to a rigid physical examination and he will be rejected for any cause of disqualification that in the future might impair his efficiency as an officer; but defects of vision resulting from errors of refraction, which are not excessive and which may be corrected by glasses, do not disqualify unless they are due to organic disease. In general the examination as to physical qualifications will conform to the standard required for recruits in the United States Army. Before making the examination the applicant will be required to submit, for the examination of the Board, a certificate as to his physical condition, which, in case no disqualification exists, will be a simple signed statement from the applicant that to the best of his knowledge and belief he is not affected with any form of disease or disability that will interfere with his proper performance of the duties under the commission for which he is applying.

No applicant will be examined who is an officer of the Regular Army on the active list, or of the National Guard, or who is not a citizen of the United States. The lower age-limit below which examinations will not be made is, for the Second Lieutenant, 21 years.

The examinations in all subjects will be oral or practical, or both; but in certain cases applicant is authorized to call for a written examination, if he so desires. Emphasis is laid upon the fact that the examination shall be specially directed to ascertain the practical capacity of the applicant, and the record of his previous service and training shall be considered a part of the examination.

Engineers, as such, are interested more particularly in the Coast Artillery, Quartermaster, Engineer, Ordnance, and Signal Corps. As a guide to the preparation required, examinations in the Coast Artillery Corps will refer to Army Regulations and important General Orders, Drill Regulations, Field Service Regulations, Explosives, Electricity. For the higher grades of the service this examination will include, in addition to the foregoing, elementary and applied mechanics, care and operation of steam boilers, steam engines, and internal-combustion engines; the theory, care, and operation of dynamos, storage batteries, telephones, and searchlights; from which it would appear that both mechanical and electrical engineers should be largely interested in the Coast Artillery work.

For the Engineer Corps the applicants will be divided into two classes:

- (a) For duty with combatant engineer troops, or other duties in the service of the front; or
- (b) For special service on the lines of communication or other points in rear, including engineer work with sea coast defenses as hereinafter indicated."

Ordinarily, officers appointed under (b) will not be assigned to combatant duties, but they will be subject to such assignment whenever needed. The reasons for this provision will appear later, when the responsibilities of the engineer officers under the two classes are considered.

Under (a), Service of the Front, an applicant for a commission as First or Second Lieutenant must be an engineer in the active practice of his profession or in some business immediately connected with or concerned in engineering matters. He must either hold or have qualified for the grade of Junior Engineer—civil, electrical, or mechanical—or of some higher grade in the Civil Service, or he must be a graduate from an approved engineering college or have been in the active practice of engineering for at least two years.

An applicant for a commission as Captain, in addition to the requirements for Lieutenant, must either hold or be eligible for the grade of Assistant Engineer in the Engineering Department at Large, or a corresponding engineer grade in the Civil Service or another Department of Government Service, or have held a commission in the Corps of Engineers of the Regular Army; or he shall be a professional engineer not less than 28 years of age, who shall have been in the active practice of his profession for at least eight years and have had responsible charge of work, as principal or assistant, for at least two years; he must have knowledge of the principles of Military Organization and Operations, in Infantry Drill and Field Service Regulations, and of the general principles of Field Fortifications as illustrated in the Engineer Field Manual.

For Major, in addition to the requirements for Captain, he must have held a commission in the Corps of Engineers of the Regular Army, not more than two grades below that for which he desires to be listed; or he shall be a professional engineer not less than 35 years of age, who shall have been in the active practice of his profession for 15 years, who shall have had responsible charge of work for at least five years and he shall be qualified to design as well as to direct engineering work. Furthermore, he must have knowledge of the duties of engineer officers and troops in war, as illustrated in the Engineer Field Manual, and in certain other publications mentioned in the Act. Under class (b), Special Services, he must be qualified for at least one of the duties assigned to the Corps of Engineers by the following extracts from Army Regulations:

"The duties of the Corps of Engineers comprise reconnoitering and surveying for military purposes, including the laying out of camps; selection of sites and formation of plans and estimates for military defenses; construction and repair of fortifications and their accessories; * * * the installation of electric power-plants and electric power-cable connected with seacoast batteries; * * * construction and repair of military roads, railroads, and bridges; military demolitions; * * * In time of war within the theatre of operations it has charge of the location, design, and construction of wharves, piers, fuel-docks, store-houses, hospitals, and other struc-

tures of general interest, and of the construction, maintenance, and repair of roads, ferries, bridges, and incidental structures, and of the construction, maintenance, and operation of railroads under military control, including the construction and operation of armored trains."

"No oral or professional examinations will be required, but recommendations of boards will be required in lieu of such examinations. Candidates will submit evidence of their actual employment in corresponding or higher positions in civil life and references to persons under whom they have been or are employed. The boards will communicate with such persons and with any others that they deem fit, and upon all the evidence submitted or otherwise obtained will base their recommendations and recommend the appropriate grades for which they deem the successful candidates qualified.

"Military experience or training in the Regular Army, Volunteers, or National Guard, or at training camps or educational institutions will be noted and reported by the board and considered in making the recommendations.

"Reserve officers from the following civilian occupations will be required for the special services of the Corps of Engineers:

Bridge engineers.

Constructing engineers (earth and concrete).

Constructing engineers (wharves, piers, and buildings).

Electrical engineers (for small plants and power-lines).

Highway engineers.

Mining engineers (skilled in tunneling and use of explosives).

Railroad engineers (construction and maintenance).

Railroad operating officials.

Sanitary engineers.

Topographical engineers."

Engineers of telephone and telegraph companies will be directly interested in the Signal Corps, examinations for which, in the lower grades, will include the same administration subjects as for the Infantry officers; also regulations and laws pertaining especially to the Signal Corps. They will be examined both orally and practically in theoretical and practical knowledge of modern methods of visual signaling, including the ability to transmit and to receive messages by flag, lantern, and heliograph.

Telegraphy and telephony include theoretical and applied knowledge of electricity and telegraphy, covering installation and repair of telephones, testing for faults, maintenance and operation of permanent telegraph, telephone-lines, and of field-lines; skill in transmission and receipt of messages on telegraph-lines; oral and practical examinations concerning dynamos and batteries, also radio-telegraphy. They will be required to have some knowledge of map-reading and field-sketching.

For Majors the examination will be the same as the foregoing, but in addition they will be required to show

knowledge as to material, cost, time, etc., and method of constructing a permanent telegraph-line in such portion of the United States as may be designated; knowledge of a scheme for assembling, organizing, and transporting a mobile telegraph-train for building light semi-permanent lines for telegraph or telephone communication under conditions to be designated by the Examining Board. They will be required to have a knowledge of engines, boilers, internal-combustion engines, and automobile traction.

For the special services in the Aviation Section, Reserve officers selected from civilians engaged in the following occupations will be needed: Aviators, aeroplane designers, motor designers, experts in aero-photography and radio-communications, aeronautical engineers and balloonists.

Probably the section of the Reserve Corps of most general interest will be the Quartermaster Corps, to qualify for which an applicant will be examined for duties that require either a knowledge of administrative and clerical detail, or for special services of a business or professional nature requiring no special military knowledge. The first class will receive a mental examination to test their fitness for the peculiar services required; the second class will not be subject to mental examination, and, as has been stated previously, neither class is subject to age limits, but both are subject to physical examination.

In the first class the scope of the examination will cover general duties as exemplified in the United States Army Transport regulations and circulars of the Quartermaster General's Office relating to supplies, payment and services, subsistence, and pay manuals. The applicant will be furnished blanks and will be required to exemplify their use in the preparation of contracts, bonds, returns, accounts current, etc. Military Law; oral examination will cover the ground of Manual of Court's Martial, the Law of War, Civil Functions and Regulations of the Military, and General Instructions for the Government of the Armies of the United States in the Field; also on the Cavalry Horse, Draft Horses and Mules—their inspection and purchase, care, feeding and watering; also the construction, lighting, and ventilation of stables; the different kinds and relative value of forage, its inspection, proper care and causes of deterioration; also on transportation by land (rail, wagon, and pack) and by water; the care of animals on cars and transports; construction and repair of roads, railroads, and bridges.

For those whose duties are not administrative there will be required merely a knowledge of and experience in one of the trades or lines of business, as follows:

"Railroad—

(a) Traffic manager, commercial.

(b) Accounting department, railroad.

(c) Operating department, railroad.

(d) Mechanical department, railroad.

(e) Other capacity, not named above, railroad.

"Navigation companies and merchant vessels—

(a) As manager.

- ☐ b) As port captain
- ☐ c) As superintending engineer
- ☐ d) As chief steward.
- ☐ e) As marine superintendent
- ☐ f) As inspector of construction and repairs.
- ☐ g) As estimator on marine repairs.
- ☐ h) As superintendent of docks, warehouses, etc.
- ☐ Auto truck transfer companies
- ☐ Auto truck freight companies
- ☐ Warehouse and terminal companies
- ☐ Animal industry
 - ☐ a) Purchasing horses and mules
 - ☐ b) Shipping horses and mules.
 - ☐ c) Breeding and raising horses and mules.
- ☐ Wholesale food and grain business.
- ☐ Wagon, machine, or other factories.
- ☐ Harness factory.
- ☐ Auto truck repair-shops or factories.
- ☐ Automobile repair-shops or factories.
- ☐ Ship construction or repair firms.
- ☐ Wholesale grocery business.
- ☐ Wholesale clothing business
- ☐ Wholesale shoe business.
- ☐ Clothing manufactory
- ☐ Shoe manufactory.
- ☐ Hat manufactory.
- ☐ Auto-truck manufactory.
- ☐ Packing houses or factories
- ☐ Shop management and its nature.
- ☐ Official of large restaurant or hotel company.
- ☐ President, secretary, or manager of any large business, whatever its nature.
- ☐ Official of any department of a large business.
- ☐ Building company
- ☐ Construction company
- ☐ Civil engineering
- ☐ Mechanical engineering
- ☐ Sanitary engineering
- ☐ Electrical engineering
- ☐ Structural engineering
- ☐ Banks or banking firms or corporations
- ☐ Financial or cashier departments of railroads or other transportation companies, corporations, or other large business concerns

"Any other industries or business not mentioned above that may make the applicant a desirable officer of the Quartermaster Corps in time of war."

The Examining Board will carefully consider the documentary evidence furnished by the applicant, and it may require additional information by personal questions as to his business experience and other pertinent matters. The Board may call also for additional documentary or oral evidence bearing on the suitability of the applicant for his commission.

Railroad officials and engineers are particularly interested in the distinction between the Engineer Corps and the Quartermaster Corps as applied to railroading. In time of war (actual or threatened) the Federal Government undoubtedly will take charge at once of all

railroads in or near the threatened territory, which will be divided into two sections, namely, the theatre of operations and the lines of communication, which, in general, is the connecting link between the field of action and the base, and through which must pass all of the men, materials and supplies required for use in prosecuting the campaign.

A railroad involved in the theatre of operations is managed and operated by the Engineer Corps; a railroad outside the theatre of operations, but involved in the line of communications, is operated by the Quartermaster Corps. Any railroad so involved must expect in such times to have on its staff, officers responsible to the War Department in either one of the corps mentioned, to represent the Department in its operation. If a sufficient number of railroad officials qualify for duty and are commissioned in the Officers' Reserve Corps in either of the sections named, the only change in its personnel that it may expect will be to see certain of its officers in army uniform instead of in civilian clothes; and conversely, a railroad in which there is insufficient representation in the Officers' Reserve Corps may expect to find army officers detailed to take charge.

When the close inter-dependence between all public utilities is considered, transmission companies and communication companies may expect to have similar situations confront them. It would appear, therefore, prudent, as a part of the general preparedness movement, that all public utility companies should encourage their officers to apply and to qualify for commissions in the Reserve Corps, and thereby insure to the companies a minimum of disturbance in administration in case of hostilities.

Engineers now have offered to them their opportunity to give their services to their country most effectively, when she will have most need of them, with the assurance that they will be given responsibility and rank commensurate with their experience and ability. Some hard digging is involved for those who have not had military training or who have forgotten much of their early experiences. The Army officers who have in hand the instruction of reserve officers do not expect us to be experienced; they expect to give us experience. All they ask of us is to be willing to learn and to give up some of our spare time to this end. In return we are assured of preferred opportunity to obtain a commission in the Regular Army, when the Army needs us, with rank and corresponding pay while on duty, appropriate to our abilities and responsibilities.

Furthermore, these same officers have given assurance that the preliminary examinations are not to be designed to keep men out of the service, but to help them to get in most effectively, that is, where they fit best. Once entered, it is up to the individual to go ahead or to stand still.

The question may be asked, why do it at all? The answer is, if there is real trouble there will be enough to go around, which means that every man will have "to do his bit."

The Ore Deposits of Mohave County, Arizona

By Frank C. Schrader

INTRODUCTION. *This region, commonly known as the Mohave district and Kingman district, lies in western Arizona in the southern part of Mohave county, and borders California and Nevada on the west. Kingman, the principal town, is situated near the centre of the area on the Atchison, Topeka & Santa Fe railway.

This region is composed of naked mountains and broad detritus-filled valleys, the southern extension of the characteristic topography of the Great Basin. In altitude it varies from 500 ft. in the south-west to 8300 ft. on Hualapai Peak south-east of Kingman.

The mountains trend north-northwest. They rise about 3000 ft. above the valleys, are generally rugged, and were formed mainly by erosion. They are composed in the main of a complex of pre-Cambrian granitoid rocks that underlies the area as a whole. Like the valleys, they average about 10 miles in width.

GEOLOGY. The rock groups beginning with the oldest are the pre-Cambrian complex, Paleozoic sediments, pre-Tertiary intrusives, Tertiary volcanics, and Tertiary (?) and Quaternary sediments. The first and third of the divisions named are the most important.

The pre-Cambrian complex consists of gray gneissoid granites. Coarse gold-bearing detrital formations, or 'wash,' locally 2000 ft. thick, partly fill the inter-montane valleys.

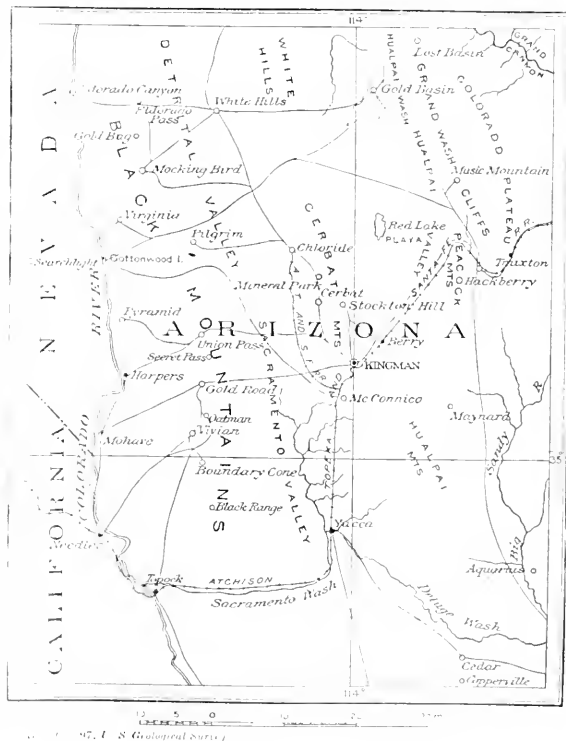

Locally intruding the pre-Cambrian rocks are pre-Tertiary igneous masses and dikes thought to be of late Jurassic or early Cretaceous age. They occur chiefly in the Cerbat mountains and are connected with the genesis of the deposits. The most important are granite-porphphy, a light gray medium-grained rock, and lamprophyric rocks, the latter occurring mainly as dark, complementary narrow dikes accompanying the acidic intrusives.

The Tertiary volcanics consist mainly of andesites, trachytes, rhyolites, and latites, lying in broad superimposed sheets, flows and beds locally aggregating 3000 ft. thick. They are best developed in the Black mountains, particularly in the southern part. They contain most of the mineral deposits of the range and played an important part in their genesis.

The beginning of mining in the Mohave area dates from the finding of ore at the Moss mine, four miles

north-west of Gold Road in the early 'sixties. From 1904 to 1914 the production was nearly \$16,000,000, of which \$11,500,000 was gold, nearly all derived from the Tom Reed and Gold Road mines. Besides gold and silver, zinc, lead, copper, tungsten, molybdenum, and bismuth are produced.

THE TOM REED-GOLD ROAD district lies about 25 miles

MAP OF ARIZONA MINING DISTRICTS.

south-west of Kingman, mainly on the west slope of the range; it comprises what was formerly known as the Gold Road and Vivian districts, the area being approximately co-extensive with the southern part of the San Francisco district of early days. The principal centres of activity are Oatman, the settlement of the Tom Reed and neighboring mines, and Gold Road, two miles north of Oatman.

Mineral was first discovered in the early 'sixties at the Moss mine, four miles north-west of Gold Road. This mine soon produced \$240,000 in gold from rich surface ore. Production has continued since the discovery of

*Abstract from paper to be presented at the New York meeting (February 1917) of the American Institute of Mining Engineers.

¹A fuller description of the rocks appears in Bulletin No. 397, U. S. Geological Survey (1909).

the Gold Road mine in 1902. Recently discoveries in the Tom Reed mine and vicinity have been attracting attention, with the result that the value of the plants and machinery at the various mines is said to aggregate nearly \$2,000,000. Some 50 odd plants are in operation. Most of them have been installed since the first of the year 1915, during which time nearly 200 companies have been organized to operate in the district, of which 150 are fully equipped and most of the others are receiving machinery. Thirty or more properties hitherto dormant have become active, and the population, which is gathered from all the mining camps in the West, has increased from 500 to more than 7000, and is increasing.

The approved method of prospecting is to sink to depth, of 300 to 500 ft. and then cross-cut and drift. Practically no surface work is done. Usually also much lateral development must be done before pay-ore in large quantity is found and the mine proved. The automobile, a prominent feature in the present activity, has taken the place of the burro in prospecting.

The cost of mining and milling is about \$6 per ton, of which \$1.25 is for power. The larger mines use electric power supplied by the oil-burning plant at Kingman. At the Gold Road mine, treating 200 tons of ore daily, the best record obtained for mining and milling is slightly less than \$3 per ton. At the Tom Reed mine, however, where 20 stamps are used, the cost is about \$6. There is said to be no profit in treating \$5 ore on a small scale. Both the Gold Road and Tom Reed mines treat their ore by the cyanide process, and have installed the counter-current decantation system.

From what has been said of the Tyro and Gold Road veins, and from the large number of other widely distributed profitable orebodies being found at depth, and the cost of mining and milling, this is not a locality for the small operator but seems rather to offer encouraging possibilities for capital to engage in deep mining.

GEOLOGY. Tertiary volcanic rocks prevail, particularly in the eastern portion of the district. They practically constitute the range, dip gently eastward toward its axis, and are in places covered by younger rhyolite, andesite, and basalt. In the southern part the green chloritic andesite is dominant, while on the west occur local areas of the pre-Cambrian gneiss, younger granite-porphry and micro-pegmatite, greenstone conglomerate, and overlying sheets of supposed Tertiary conglomerate, younger gravel and lava flows. Locally intervening between the pre-Cambrian and the overlying volcanics are occasional patches of tilted and metamorphosed Paleozoic limestone and shale belonging to the Grand Canyon section. These sedimentary rocks are not as yet known to have any bearing on the deposits or on mining other than to indicate to the miner the lower limit of the volcanics.

Recent mine developments show that the geology of the ore-bearing volcanics is more complicated and seemingly of more importance than was at first supposed.

In the vicinity of Vivian, and from there toward Oatman, occurs the older or basal andesite, which is light

gray, calcitic, 300 ft. thick, and rests mainly on the pre-Cambrian complex and Paleozoic sediments. The older andesite, however, is not known to be of wide extent in the district, a fact overlooked by Bancroft and others. It is absent from Secret Pass where the next higher rock, the green chloritic andesite, rests directly upon the pre-Cambrian granite, and from the Hardy mountains, where the green chloritic andesite similarly rests upon the Mesozoic granite-porphry or micro-pegmatite.² It is not known to be present at the Gold Road mine, and according to Sperr³ the rock underlying the green chloritic andesite in the deep workings of the Tom Reed mine does not correspond with the older andesite described at Vivian. The older andesite is succeeded unconformably by another series of flows, the green chloritic andesite, which contains an important part of the mineral deposits in the Tom Reed-Gold Road district. The flows aggregate a known thickness of 800 ft. The rock consists mainly of a greenish fine-grained groundmass containing abundant whitish feldspar phenocrysts. It is chloritic and calcitic. It is intruded by black latite and younger lavas.

The intrusive nature of the green chloritic andesite and association of ore deposits with its intrusive phases in various parts of the district are also abundantly corroborated off from the main mass, extend $\frac{1}{2}$ mile or more westward into the older andesite. A black fresh-looking specimen of it from the Leland mine proved to be latite; it contains chlorite in abundance throughout.⁴

The intrusive nature of the green chloritic andesite and association of ore deposits with its intrusive phases in various parts of the district are also abundantly corroborated by the later work of Sperr, Probert, Bancroft, and other engineers. Probert⁵ believes it to be both intrusive and extrusive, that dikes and sills of it occur in the older andesite, and that mineralization is dependent upon this association.

Bancroft⁶ writes that in the vicinity of the various mines which he examined he found evidence of the intrusive nature of this formation, and that the orebodies are largely formed within the intrusive.

More recently, according to Smith,⁷ the bottom as well as the collar of the Tom Reed shaft at 1075 ft. in depth was in the green chloritic andesite, which in the bottom of the shaft was ore-bearing, and he suggests that the rock may here be intrusive. The supposition of the rock being here intrusive, probably as a neck, would help to account for the unusual thickness of the formation at this point, which seems to be local, since elsewhere in the

Tom Reed mine and in the neighboring United Eastern, Pioneer, and other properties the workings, according to Schader,⁸ passed through the green chloritic andesite and into the older underlying andesite at shallower depths and have workable ore in the lower rock.

Therefore, according to the observations of six or more investigators, the green chloritic andesite includes rocks that vary considerably from the normal andesite, rocks

with which the ore deposits in general seems to be associated and which are known to be intrusive into the older andesite. The most important of these rocks seems to be the dark latite at the Leland mine and elsewhere. It seems to intrude not only the older andesite but also the green chloritic andesite as sheets, necks, and dikes, and to be intimately connected genetically with the ore de-

⁸J. D. Sperr: 'Conversational Geology at Oatman,' *Eng. & Min. Jour.*, vol. 101, No. 26, p. 1119 (June 24, 1916).

⁸Carl F. Schader: Personal letter, Feb. 6, 1915.

posits. More recently, Sperr⁹ regards all the commercial ore as occurring in the andesites intimately associated with latites. The intrusive nature of the rocks associated with the ore deposits obviously favors continuity of the deposits in depth.

The deposition of the green chloritic andesite was followed by a period of great fissuring and faulting accompanied and followed by eruption of the next higher group, the undifferentiated volcanic rocks 2000 ft. thick, containing the Gold Road and other important veins, and by intrusions of younger rocks, especially latite and rhyolite in the form of dikes, necks, and rounded plug or stocklike masses, and the making of many of the larger fissure veins. The undifferentiated volcanics are succeeded by a series of younger light-colored tuffaceous rhyolites locally 1000 ft. thick, known as the 'water rock,' succeeded by dark reddish andesite, which in turn is followed by black olivine-basalt, the youngest of the effusive rocks, which remains as a cap over a large part of the Black Mesa mountains.

THE ORE DEPOSITS, which are numerous, are chiefly gold-bearing fissure-veins. They vary from 5 to 70 ft. in width and from a few hundred feet to several miles in length. In general they are strong and persistent. They strike north-west with steep dip north-east. They are almost devoid of metallic sulphides, the gold being free. They occur chiefly in the lower part of the undifferentiated volcanic series, the green chloritic andesite, the granite-porphry, and micro-pegmatite, other underlying rocks, and also along contacts where latite and rhyolite are the intrusives. Some of the deposits are rich, but the large bodies of low-grade ore constitute the main resource. Ore having a metallic content of \$10 or less is considered low-grade.

The older andesite, from the ill behavior and feathering out of certain vein deposits on entering it from the green chloritic andesite, was originally regarded by me as unfavorable for mineral or essentially barren, particularly in the Vivian district. Owing to its tuffaceous brecciated and fragmental nature it is almost devoid of lava cooling shrinkage-cracks and fissures, which elsewhere form favorable repositories for ore. According to Palmer¹⁰ "the occurrence of any ore shoots in the earlier (older) andesite is yet to be demonstrated." E. W. Brooks also limits the area of commercial mineralization in this part of the district to the green chloritic or 'younger andesite.' Later developments, however, in the Oatman and Vivian camps, disclose workable ore deposits in the older andesite also. My belief that major veins probably occur in and below this formation is shown by the following statement: "The veins cut through the great mass of Tertiary volcanic rocks which characterize the range and undoubtedly continue in depth into the underlying pre-Cambrian granitic rocks."¹¹

According to Palmer,¹² "there is no doubt that the

veins extend into the pre-Cambrian and some ore of value has been found therein."

Since the deposits are confined to the vein-filling and do not as a rule form metasomatic replacements in the wall-rock, as at Cripple Creek, the selective preference which any bounding wall-rock, by reason of its more favorable physical or chemical properties for replacement, may exert in favor of ore deposition seems to be practically nil. Accordingly, there is no apparent reason, other conditions being equal, why the deposits should not be equally developed in any one of several formations through which the fissure-vein with like strength may extend.

The deposits consist of two types: those in which the gangue is chiefly quartz and adularia, and those in which it is chiefly calcite. The source of the quartz and adularia is referred to the silicious magmas and that of the calcite to basic or andesitic magmas with possible contributions derived from underlying limestones. The former carry the best ore, occur mostly in the undifferentiated volcanic rocks and in granite-porphry and have a general north-west south-east trend. The latter seem to occur mainly in the green chloritic andesite and trend more nearly north-south. Among the most important of the former type are the Gold Road and Tom Reed veins; among the latter, the Pasadena, Mossback, and Meals. In some cases the veins are associated with boldly cropping silicified dikes of which the deposits in certain instances may be a part replacement.

According to Platts,¹³ the most productive veins, such as those in the Tom Reed, United Eastern, and Big Jim mines, are in a complicated series of fissures, part of which strike about N 45° W, and others N 60° W, producing with each other a conjugated system with numerous intersections near which many large orebodies are found.

Superficially, the veins seem to fall mostly into four main belts,¹⁴ which, named in order from north to south, are the Gold Road, Tom Reed, Vivian, and Black Range. The Tom Reed belt is the best developed and contains the most interesting discoveries.

There seem also to be two or more horizons or vertical 'ore-zones.' The largest and richest orebodies seem in general to lie in a zone of enriched oxides between the 300-ft. and 500-ft. levels. Below this zone the ore decreases in value, but continues to be of workable grade beyond the deepest point yet penetrated. The richness of this zone as suggested by Smith¹⁵ is probably due to secondary enrichment, by contributions leached from shallower depths, in support of which the presence of vugs and manganese oxide in the upper part of the veins is cited. This view is also corroborated by the tendency of the zone to parallel the contour of the surface. For instance, its occurrence at about the same distance from the surface in the Gold Road mine as at Oatman, though

⁹Leroy A. Palmer: 'The Oatman District, Arizona,' M. & S. P., vol. 113, No. 6, p. 195 (Aug. 5, 1916).

¹⁵*Op. cit.*, p. 173.

at correspondingly greater elevations and higher geologic horizons. The gold was probably precipitated in large part along with the manganese oxide.

If the thickness of 600 or 800 ft. assigned to the green chloritic andesite be correct, this Oatman ore-zone, or, more generally speaking, the triangular area of several square miles comprised between the Tom Reed, Pioneer, and Pasadena mines, should lie mainly in this formation. There seems to be also present, notably at Oatman and vicinity, a shallow or surface zone of leached oxides to which pay-ore found at or near the surface is generally confined. It extends to depths of about 150 ft., between which and the zone of enriched oxides, or 300-ft. level, lies a 150-ft. intermediate zone of leached or relatively barren ground, although the valuable ore-shoots, according to Sperr,¹⁶ almost without exception come at least within 100 ft. of the surface.

These two zones have probably suffered about the same amount of leaching, the upper zone certainly not less than the intermediate or barren zone. The upper zone appears to owe its greater ore-content to the more silicious, and consequently resistant, character of the ore, which accordingly better withstands the process of leaching.

As against the view of enrichment by leaching and re-deposition in the main zone of Platts¹⁷ who holds that the ore is essentially a primary deposit formed by hot ascending solutions, that from the nature of the gangue it is evident that acid solutions could not exist, and that, except for the oxidation of the pyrite, there is no evidence of the action of surface-water on the ore.

It seems quite possible, as suggested by one writer, that the ground-water table in the district may be in part dependent upon the neighboring Colorado river. If this view be correct, physiographic study will probably be able to correlate certain horizon features of the vertical section such as leaching, with relatively prolonged pauses in the historical down-cutting of the river. It does not, however, seem safe to assume that the water-table at Oatman coincides with the level of the Colorado river, which is 2000 ft. lower than Oatman, and that therefore the ores, if they persist downward, will continue to be oxidized and of the same milling character to that depth as advocated by Palmer.¹⁸ Owing to the greater elevation of the gathering zone on the east, which probably extends to the Hualapai mountains, or longitude of Kingman, the ground-water table is not a level surface, but gradually rises from the Colorado river, eastward, and at Oatman it probably stands several hundred feet above the level of the river.

The ore occurs chiefly as a series of tabular or lenticular ore-shoots pitching variously within the vein, with which they exhibit some degree of parallelism. The shoots vary from 1 ft. wide to the width of the vein. They usually carry gold for their full width. They

range up to nearly 1000 ft. in length and depth, and there is a general similarity or repetition of the shoots in the same vein. They seem to have been formed by thermo-aqueous processes that followed igneous activity. In general, the quartz and values favor the hanging wall, which is generally the better defined, and contains stringers branching off obliquely from the vein, while the spar or calcite favors the foot-wall. The gold is mostly associated with the quartz-adularia gangue and not rarely where sulphides have existed, it, according to Platts,¹⁹ occurs in hematite (which is pseudomorphic after pyrite) in the quartz.

According to Palmer,²⁰ the first indications of the vein encountered in sinking are small stringers of quartz and calcite scattered through the andesite, usually accompanied by slight pyritization in the vein-wall andesite which yields a little free gold in the pan, while in the ore-shoots the vein matter shows pronounced hematite and manganese stains. It is said that the problem in development is not so much the finding of veins as the discovery of ore-shoots in the veins, that nothing sufficiently tangible has yet been found to use as the basis for a theory to guide the operator in the search for ore.

Though no rigid rule can be laid down to guide the operator in search for ore, nevertheless, from the apparently well-established facts that the metallic values have been largely imported by the replacement quartz-adularia solutions and that more gold is found where the replacement of calcite is most nearly complete, in formulating plans of exploration much benefit in most cases should be derived from a correlative study of the criteria indicating the probable courses followed by these solutions, namely, quartzose vein croppings, silicified wall-rock, the quartz pseudomorphic structures, etc., which have been described. It was the quartz adularia or silicious waxy-appearing character of the deposits seen in the Tom Reed mine and the recognition of their marked similarity to the then-producing deposits of the Gold Road mine that apparently led to the resumption of operations in the Tom Reed mine.

THE mine of the Vermont Copper Company at South Strafford, Vermont, is one of the oldest mines in the United States, having been first opened in 1793. The ore was mined to make copper sulphate and over 1300 men were employed at one time. More recently it has been operated intermittently as a copper mine, but owing to difficulties in smelting at each attempt, the mine was shut-down. The ore is pyrrhotite, carrying 2 to 2.75% copper as chalcopyrite. Some experiments were made last spring in treating this ore by pyrite smelting, and these experiments were successful. The mine is now under development to increase the tonnage available before further improvements are made.

TAILING is treated in Cornwall for its tin-content, and during August, 10,876 tons yielded 37.3 tons of black tin, containing 70% metal.

The Importance of Efficient Settling of Slime

By Paul W. Avery

In many cyanide plants where fine grinding is practised, the thickening of the slime to a 1:1 or a 1:1½ ratio (solid : liquid) is often a serious problem. I say 'serious' because a thick pulp for the filters is imperative in order to secure quick filling and a good uniform cake. It is also serious from the standpoint of dissolved metal, cyanide, and water losses.

The filter-press in many slime plants is the determining factor of the daily tonnage to be treated, and every condition that tends toward shortening the press-cycle with good results metallurgically, is most desirable.

Thin pulp-feed decreases filter-press capacity, sometimes to an alarming degree. In one instance observed by me, 30 minutes was required to charge with a thin pulp and only 10 minutes with a thick one. Sometimes thin pulps are the result of carelessness on the part of the mill-man, he deeming it an unnecessary detail to take specific gravities at regular intervals. It is quite a simple thing to make this only a matter of routine. In Mexico and in Central America I have trained *peones*, who could hardly read or write, to take specific gravities with accuracy. We were able thereby to control the work of the thickening devices to a notable degree.

To me the securing of a thick pulp for press-feed is the most important thing in shortening the cycle. Just how to secure a thick pulp is a puzzle when one finds by experiment and actual mill-runs that the economic limit of slime-settling is around 1½ or 2:1 (S : L) on continuous discharge from the Dorr thickeners.

Manufacturers of filters usually insist that the feed must be 1:1 or better to get the requisite capacity out of their press. Often upon starting a new plant, to the chagrin of all concerned, the press falls down on its rated capacity by 25% or more. Blame is placed immediately by the mine management on the manufacturer of the filter, who, to vindicate his claims, sends a

representative to straighten out the difficulty if possible. Nine times out of ten he finds that the changes necessary are not in his department, but in the thickening end of the plant, where perhaps he discovers the specific gravity of the press-feed to be around 1.25 or 1.30, requiring three times as long to charge the press as with a feed of 1.45.

This factor is most important, and is often disregarded by mill-men. One small plant, which I investigated recently, raised its tonnage nearly 100% by close observance of this important detail. In order to find the economic limit of settling of a slime, I think the method described by M. D. H. Forbes in the *Engineering & Mining Journal* of February 24, 1912, is a good one to follow. In the March Bulletin of the American Institute of Mining Engineers, H. S. Coe and G. H. Clevenger have a splendid paper on the latest research in this department of cyanidation.

I shall give a brief outline of how we determined the economic limit of settling on the several slimes we have at this property and the changes we are making in the hope of overcoming the conditions previously outlined.

Seven different slimes were treated in the series of settling tests, the results of which are plotted in the large curves on the left-hand side. These slimes have the following names: San Carlos Sulphide, Oxide Slime Dump, Sand Dump, Descubridora, San Rafael Hanging-Wall Fills, West Vein Sulphide Fills, Main San Rafael (virgin ore). The ordinates are represented by percentages, namely, the volume of the clear water in centimetres divided by the volume of the pulp in centimetres, the abscissa being represented by dilution of the pulp or grams of solids per litre.

The following (Table I) is a tabulation of the tests on one slime from which the corresponding curve on the diagram was plotted. It will be observed that tests

were conducted both with and without an electrolyte, which with this slime produces a marked effect on the rate of settling.

I give another tabulation showing that the addition of lime has a marked retarding effect on the slime settlement, that is, the settling in pure water is more rapid than with the electrolyte. This is the only slime here (at El Oro) that exhibits this freak phenomenon. (See Table II.) When this slime is mixed with other slimes in the following proportions, the presence of lime has almost the same retarding effect as the slime alone.

SLIME MIXTURE

	%		%
Old West vein-fill.....	60	Sand dump	10
San Carlos	5	Slime dump	25

It appears from the above that, other things being equal, the use of excessive alkalinity is a serious mistake.

Even with slimes that settle well with lime, an excess of the latter increases the viscosity of the solution, which in itself retards settling. This anyone can prove to his own satisfaction.

After the curves had been plotted, the points where they cut the 5% efficiency line were noted and these points were then placed in the settling scale (an arbitrary scale in the upper right-hand corner) to fix their settling number. For example, the San Carlos curve cuts the 5% efficiency line close to 400 gm. per litre, which corresponds to a settling number of 1. This number placed on the settling cross-section scale immediately below corresponds to one square foot per ton of dry slime. In this manner the approximate area of tankage was computed for certain mixtures of slimes expected in the daily routine of the plant. It will be seen, however, in studying the large curves that the majority

CURVE II. RELATION OF PULP-THICKENING AND FILLING-TIME.

metric tons. An increase in pressure of 1 lb., or a total of 30 lb., raises the tonnage per cycle to 19.2. In the case of the 1:2 pulp, with a pressure of 26 lb., the press will receive 15.15 tons, with conditions using the same and charging at 30 lb. the press will receive 15.9 tons. A change in our flow-sheet has enabled us to increase our filling pressure, which will no doubt be found advantageous when the plant is running again.

In order to approach the 1:1 pulp we decided upon intermittent discharge of the thickeners, in place of the continuous system. Intermittent discharge may be accomplished in several ways either by using some mechanical device for opening and closing the discharge-valves or with an electric mechanism giving an overload-alarm that rings when the rakes are plunging through a heavy charge of slime. This latter may be made automatic as well (Dorr electric automatic device) or it may be operated by an attendant, who, when warned, discharges the tank until the alarm stops ringing or an electric light goes out. The following is a sketch of the automatic rig for opening and closing the discharge-valves on all our thickener tanks.

According to *The Mining Magazine*, the Anaconda has also designed an automatic opening and closing device for intermittent discharge; the Dorr Company furnishes an automatic device with their tanks if desired.

Our tests show that in order to obtain a 1:1 pulp, time must be allowed for the upper layers or zones of slime to

- A Worm-gear on Dorr tank.
- B-B' Arms with friction-clutches clamped to central shaft. One opens the valve and the other closes it.
- C Spur-gear.
- D Pulley keyed to shaft E. This pulley makes about a 90° turn in one direction when clutch C passes over and a 90° turn in the opposite direction when clutch C passes under.
- E Horizontal shaft.
- F Bevel-gears.
- G Plug-rock connected to vertical shaft.
- H Launder carrying thick pulp.
- I Discharge pipe connected to bottom of tank.
- J Rakes.
- K Vertical shaft.

Note Arms B and C should be set after determining experimentally the time required for settling and the time for discharge of the thickened pulp in order to secure the desired specific gravity of discharge.

CURVE I. SETTLING-RATIOS OF SLIMES FROM TABLES I, II, AND III.

flatten out toward the zero efficiency line at a dilution of 534 gm. per litre or a solid to liquid ratio of 1:1 $\frac{1}{2}$. This we found to be the case in actual practice. If special care was taken we could obtain pulp with a solid to liquid ratio of 1:1 $\frac{1}{2}$, but averages over weeks and months showed ratios close to 1 $\frac{3}{4}$:1. With such a pulp-feed from 20 to 30 minutes were required to charge the Merrill presses. After considerable work with a small filter-press and monteju equipment in our metallurgical laboratory, we found by thickening the pulp to 1:1 it was possible to charge in one-third the time (see Curve II). In this set of curves it will be noted that three degrees

of thickness of the slime were tried, namely, 1:1 $\frac{1}{2}$, and 1:2 (S : L). In four minutes of filling time a 1:1 pulp will charge (calculated from tests) the large filters with 16.2 dry metric tons; a 1:1 $\frac{1}{2}$ pulp, with 13.8 tons; and a 1:2 pulp with 12.2 tons. The gain in tonnage per cycle with the 1:1 pulp over the 1:2 pulp is 4.0 tons. With about 80 cycles per 24 hours the total gain will be 320 tons.

It may be interesting to call attention to the tonnage effect of increased pressure in filling (see Curve II). After 10 minutes' charging with 1:1 $\frac{1}{2}$ pulp at 26-lb. pressure, the average large filter will receive 17.3 dry

minge with the lowest, thus causing compression with a removal of interstitial fluid. As shown clearly by Clevenger and Coe, the degree of thickening in the compression zone is a function of time. This law was proved here in actual practice on a pyritic concentrate, 99% of which passed a 200-mesh screen. About 15 tons of this concentrate was ground daily in a special circuit of its own. It was necessary, on account of limited tank-capacity, to get this pulp as thick as possible. Continuous discharge gave a pulp of 1:3 solid to liquid ratio.

By closing the discharge-valve and allowing the tank to settle for as long as eight hours we secured a pulp with a moisture content as low as 45%. In cases like this an overload alarm would be the correct thing to use. The spring could be set to give the alarm when the rakes had picked up a pulp dry enough for discharge.

Concentration of Molybdenum

Treatment of molybdenite is not an easy problem, according to Herman Fleck of the Colorado School of Mines. Nearly everything has been tried of an ore-dressing nature on the molybdenum ores, no two of which are alike—and, on the whole, with surprisingly interesting results. Molybdenite is different from most minerals. It is heavy like a metallic sulphide and behaves in part like these, and then it is flexible, and not brittle, with strong basal cleavage and a tendency to flake like graphite or mica. Ordinary methods of concentration are hardly applicable. Complex ores, therefore, add to the metallurgist's troubles, and the physical condition of the molybdenite is another consideration. This is as follows: 1. coarse flaky pieces or particles; 2. fine flaky particles or grains; 3. both 1 and 2; and 4. thin flakes or filmy coverings.

The nature of the gangue material plays an important part. A filmy molybdenite deposited in seams of a hard quartz is an extreme example of refractoriness. A coarse-grained granite or pegmatite, carrying coarse mineral, is the other extreme. When associated minerals, pyrite, chalcopyrite, bismutite, native bismuth, claudonite, their oxidation products, or men and pyroxene, or perhaps several of these are present in either of the cases above, the problem becomes complex. However, combinations of heat, newer principles, such as flotation, magnetic and electrostatic separation, have done much to recover good concentrate from ore that was looked on unfavorably a few years ago. Only rarely does the mineral occur so coarsely divided that it may be hand picked.

Low native wages on the Rand has not resulted in notably low working costs, though the ratio of labor cost to total cost is somewhat below the probable average, according to H. F. Bain, who recently studied conditions in that region. Native efficiency is low, requiring highly paid supervision. One white man is paid more than 8 to 10 Kaffirs.

Output of the Disseminated-Copper Mines

Reports of the four porphyry copper companies for the third quarter of 1916 will soon be available, from which interesting abstracts will be obtained. Meanwhile a comparison of the yields for the first 9 months of 1916 and 1913 is worth study. These are as follows, in pounds:

	CHINO

August	20,315,140	10,620,981
September	20,462,256	11,817,428

In several cases the monthly outputs in 1913 will be found equal to those in 1916, but the rate of production in November of the current year is far in advance, being practically the limit, until additional plant under construction is completed.

PALÉONTOLOGY is a highly specialized branch of geology, and many economic geologists have at most no more than a superficial knowledge of this science. When accurate determinations of fossils become necessary in order to fix the geological age of certain strata, such engineers and geologists usually submit the fossils they may have collected for this purpose to experienced paleontologists.

Two Washington Mining Districts

By Robert E. Brinsmade

INTRODUCTION. In opposite corners of the State of Washington there are two mining camps comparatively unknown to the outside world, in spite of considerable expenditures for development. The first, in the north-east corner, is that of Metaline Falls; the second, in the south-west corner, is that of Bald Mountain.

Metaline Falls is a town of 2000 people and is the terminus of the Idaho & Washington railway at a point 127 miles north of Spokane, and at an elevation of 2000 ft. above sea. The town lies on the east bank of the Coeur d'Alene river, which is the only stream of the district and forms the central feature of the mountainous landscape. The country-rock of the valley-bottom and adjoining cliffs is limestone, which rock, with some valley-clays, furnishes the raw material to the 1000-bbl. plant of the Inland Portland company at Metaline Falls. Of the metal mines, the only producer is the Larsen, but the Oriole, the Shellenberg, the Grandview, the Morning, and the Riverside are partly developed. Of these, only the first two lie on the west side of the river, and all save the Oriole are in the limestone formation.

THE LARSEN property follows some low hills on the west bank of the river. The first work at this mine was done some years ago by prospectors who sank a 45-ft. vertical shaft to a small zinc vein and then followed the vein down a short distance by an incline. When the property was re-opened last year, the old work was found to have been done on a branch vein and the recent output has been obtained from an open pit a hundred yards south. The open work has excavated the ore from the surface to the 50-ft. level, where the vein appears to be a fissure, 15 ft. wide, striking north and dipping 60° west. The vein has well-defined limestone walls, with a filling of quartz and calcite, showing a dissemination of small crystals of sphalerite of the resin-jack variety. Near the surface there appears white smithsonite, and small bunches of galena occur at intervals in the vein among the crystals of zinc.

The open pit is bounded on the south by a fault and extends 50 yards north. The broken ore, with little or no sorting, is drawn from the pit to the mill in trains of four 2500-lb. cars, by a Percheron horse over a tramway of 18-in. gauge and a quarter-mile long. To develop the vein below the pit-floor, the tramway has been extended north along the hillside to a new inclined shaft, which is being sunk on the vein about half-way between the south fault and the aforesaid prospector's shaft to the north. The new shaft has two compartments and is operated by an electric hoist. In fact, all the power for mine and mill is now supplied by wire from the hydro-electric

plant of the cement works at Metaline Falls, the current in use being 440 volts, 60 cycles, and 3 phases. For rock-drilling, hammer-drills are used, fed with air by a belt-driven compressor.

The mill-building is a wooden structure built in two parts on a hillside. The upper half contains the sorting-house and rests on a gentle slope whence there is a sharp drop for 50 ft. down a cliff to the washing-house at the foot of the hill above the wagon-road. In the sorting-house there is only a 9 by 14-in. Blake jaw-crusher, which discharges onto an 18-in. rubber sorting-belt 15 ft. long, whence the ore is spouted dry to the washing-house. Here the ore enters a Chalmers & Williams ball-mill, 6 ft. long, 5 ft. diam., running at 29 r.p.m., the discharge

MAP OF THE STATE OF WASHINGTON

being lifted by a rubber bucket-elevator and divided for screening to 14-mesh between a 3 by 6-ft. trommel and a Wood revolving conical screen. The screen-oversize returns to the ball-mill, while the undersize is dewatered by an inclined drag-conveyor made of angle-iron scrapers bolted to a 10-in. rubber belt. This last discharges the dewatered pulp into a rising-current classifier. Five classifier-spigots each feed an Overstrom sand-table, each of which produces a lead heading, a zinc middling, and a tailing that descends to the settling-pond. The classifier-overflow runs to two 9-ft. Callow cones, the settling from which is treated on 11 Overstrom slime-tables; these last yielding the same lead and zinc products as the sand-tables, and a tailing that accompanies the overflow of the Callow cones to the settling pond. The lead heading and zinc middling of the Overstroms are both shipping products and they fall to wooden bins on the lowest level. Here, after drainage, they are shoveled into steel Koppel self-dumping boxes mounted on four-wheel wagons, which are hauled by horses to the gasoline motor ferry at the town of Metaline, and transferred to the

*Consulting engineer, Puebla City, Mexico.

railroad box-cars, waiting across the river at Metaline Falls, to be taken to the Missouri smelters. The zinc concentrate assays 50 to 54% zinc; this leaves a good profit at present, in spite of the high freightage of about \$12 per ton. The lead concentrate is only 10% of the shipment and is thus insignificant in quantity. The mill was started in August 1915, and has since then been handling 2500 to 2800 tons per month of crude ore assaying 8 to 14% zinc. It is planned later to erect a flotation plant to re-treat the tailing now being stored in the settling-pond.

THE ORIOLE mine is two miles north-west of Metaline, and is owned by the Metaline Oriole company of Spokane. The mine is situated on the east side of a gulch running north into the quartzite hills on the west side of the limestone valley of the Pend d'Oreille river. An adit has followed the vein eastward for 880 ft. and midway is connected by an incline-shaft with the surface. The vein is a fissure 1 to 6 ft. wide, it dips 50° north, and is filled with quartz containing galena, sphalerite, pyrite, and chalcopryrite. The sorted ore runs 35% each of zinc and lead, 30 oz. of silver, and a little copper. Such a composition means a hard nut for the smelter and necessitates some sort of separation at the mine before shipment.

SHELLENBERG. The development here consists of a number of shallow shafts or pits on the top of a 300-ft. bluff east of the river and a mile north of Metaline Falls. The outcrops opened by the pits show quartz pockets, up to 30 ft. long and 20 ft. wide, with a sprinkling of galena nodules. The ore on the dump runs from 20 to 60% lead, but, like all the galena of this district, it is poor in silver, containing only 2 or 3 oz. per ton.

GRANDVIEW. This prospect lies on the bluff north of the Shellenberg, and is developed by two adits driven east into the face of the cliff above the river. The first adit discovers nothing in its 50 ft. of length, but the other adit cuts a cross fissure at 75 ft. from its mouth, and by a stope driven upward, farther in, reveals a clay-like filling interspersed with large boulders of quartz and galena.

MORNING. This property is opened by a 100-ft. vertical shaft placed 100 ft. above the river and three miles north of Metaline Falls. Besides two adits almost a mile of underground cross cutting and driving has been done from the shaft at the 80 ft., 200 ft., and 400 ft. levels. This work has been done with a view to exploring in depth the outcrops of galena, but so far the mine has not become a shipper. Besides the hoisting house, office, and bunk house, there is a complete equipment of machinery. A horizontal return tubular boiler of 80 hp. supplies steam for the second motion single drum hoist, which handles the ore bucket, and for a 5-drum straight line compressor, which supplies air for drills and pumps. The 400 ft. level is more than 200 ft. below the level of the river, and the seepage is from 60 to 100 gallons per minute, according to the season.

RIVERBANK. This ground lies four miles north of the Morning mine and is opened by an adit driven into a

300-ft. limestone cliff on the east side of the river, at a point about half-way to the top. At the mouth of the adit there is an outcrop of iron ore showing bunches of galena, but this was soon penetrated, when opened a few years ago, and as no more ore could be discovered, the mine was shut-down.

THE BALD MOUNTAIN district is in Skamania county, near the north bank of the Columbia river. The railroad station is Cape Horn, on the Great Northern system and only 30 miles north-east of Portland, Oregon. The mineral zone lies in the foothills of Mt. St. Helena, a prominent peak in the western Cascades. Unlike the Metaline Falls region, this district, as far as observed, shows only igneous rock, covered by a cap of lava of the basaltic type. The topography, though bold, is rounded and well adapted to the growth of huge firs and other conifers, which densely covered much of this country as late as 20 years ago, but which has recently been decimated by forest-fires and the woodman's ax. To reach the mines one must climb the hills north of Cape Horn for a distance of 20 miles horizontally and over 1500 ft. vertically. The best wagon-road follows the gulch of the Washougal river and occasionally changes from one bank to the other over plank-bridges often supported by single spans of huge logs. As one ascends into the hills, signs of extensive and reckless lumbering appear in the forest: not only have the bulk of the trees been killed by fires, but huge sound logs everywhere strew the ground as they were left to rot by the careless cutters. At intervals appear crib-dams that served to supply the artificial floods necessary for floating the logs down-stream to the Columbia river.

The mineral zone is being developed by three companies: the Washougal Copper & Gold Development, the Skamania, and the Washougal Gold & Copper. The mines lie within the space of a league and the workings delve into hills of brown andesite from the vantage-points offered by narrow gulches with high steep sides.

WASHOUGAL COPPER & GOLD DEVELOPMENT Co. This property is the least developed of all, [despite its name, *Error*] having only a 400-ft. adit, but the large expenditure incurred this summer for the repair of the wagon-road to Cape Horn indicates a renewal of activity.

SKAMANIA. This ground is opened by a 1300-ft. adit and a connecting shaft 575 ft. deep. Shipments have been made to the Tacoma smelter, and some recent assays of sorted ore gave the following results:

Lot Number	Copper %	Silver oz.	Gold oz.
1	18.2	15.2	0.02
2	23.5	13.4	0.01
3	15.8	8.7	0.01
4	21.6	18.5	0.02
5	19.4	15.6	0.18

WASHOUGAL Gold & Copper Mining Co. This is the most extensively developed mine of the district and the only one having a mill. Here are two parallel veins on opposite sides of the narrow gulch of Shirt creek, a branch of the Washougal river. Each vein dips about 70° into the hillside and follows closely the westerly

course of the gulch. The veins are strong fissures varying in width from one to six feet but the filling, save in the shoots or chimneys, is only barren country-rock. These chimneys are of quartz, they vary in length from 20 to 40 ft., and contain chalcopryrite, bornite, and sphalerite disseminated in bands of minute dispersed crystals. The sorted ore resembles, in the ratio of its content, the assays given for the Skamania mine, having about 1 oz. of silver to 1% of copper, but each unit of copper is here accompanied by $1\frac{1}{2}$ units of zinc.

Each vein is entered by a main adit from the bottom of the gulch, started at 1700 elevation or some 400 ft. below the outcrop. The north, or Dixie, vein is cut by a 400-ft. adit, and is then followed to the west for 1200 ft. by a drift. At the north end of the adit is a 130-ft. incline-shaft. No underground communication yet exists with an upper adit and drift that explore the vein at 1850 ft. elevation. The south, or Copper King, vein is also cut by a 400-ft. adit, but here the chimneys are more frequent, so that the drift has been extended west for over 2000 ft. along the vein. Near the west end an incline-shaft has followed the vein down for 130 ft. and opened up the best ore in the mine.

This property is fully equipped with buildings and machinery. There is an office, a cook-house, and several bunk-houses, as well as the mill and repair-shops, all placed in the gulch below the main adits. Power for the mine is furnished by a 36-in. Pelton wheel, which takes its water, under 365 ft. head, from a wooden flume heading in Shirt creek. As the snow falls here to a depth exceeding 10 ft., there is plenty of water for power except during the summer, when steam-power is used. Drilling is done by hammer and piston drills supplied, like the mine-hoists and pumps, by an Ingersoll-Rand belt-driven compressor of No. 10 type and of size 12 by 12 by $7\frac{1}{2}$ by 12 in. For cutting cordwood for the three boilers, aggregating 140 h.p., and ripping boards for the buildings, there is a small saw-mill that is fed by logs hauled directly from the forest-clad hillsides by a steam-winch.

The concentrating mill is yet in the experimental stage, the product being low in copper, and the tailing rich. The flotation process will have to be tried. There are now installed a 7 by 10-in. Blake jaw-crusher, two Nissen stamps, a Pierce amalgamator, a cone-classifier, a Wilfley table, and a Frue vanner, all actuated by a 10 by 14-in. horizontal steam-engine. The silver of the ore will not amalgamate, but laboratory tests have shown that it can be saved, along with the copper and zinc minerals, by flotation.

THE MINING BUREAU of the Japanese Department of Agriculture and Commerce has decided to institute researches for mineral deposits throughout that country, and will ask for the appropriation of 88,000 yen (1 yen = 50 cents) to be included in the budget for the fiscal year of 1917. Of the amount, 32,000 yen is said to be appropriated for carrying on a geological survey of principal oilfields.

Phosphate Rock Mining

*Reserves of phosphate in the United States are estimated as follows, in long tons:

Eastern States:

Florida	227,000,000
Tennessee	88,000,000
South Carolina	9,000,000
Kentucky	1,000,000
Arkansas	20,000,000
	<hr/> 345,000,000

Western States:

Montana, Idaho, Utah, and Wyoming.....5,367,982,000

Total5,712,082,000

During 1915 there was marketed 1,835,667 tons, valued at \$5,413,449. This was a decrease of 33% in

MAP SHOWING PHOSPHATE ROCK DEPOSITS OF THE UNITED STATES.

quantity and 44% in value compared with 1914. The War was responsible for this, restricting exports. The total quantity mined was 1,358,611 tons in Florida, 389,759 tons in Tennessee, 83,460 tons in South Carolina, and only 3837 tons from Idaho, Utah, and Wyoming.

Exports amounted to 253,549 tons, worth \$6.33 per ton, a decrease of 710,565 tons. From 1905 to 1915, exports of phosphate rock were 40% of the total 50,293,573 tons mined. The highest grade shipped contains 77% calcium phosphate, with 3% or less of iron oxide and alumina.

Simple field tests for phosphates are given by W. B. Hicks. The best method is to moisten the fresh rock surface with a drop of nitric acid, and then place a small crystal of ammonium molybdate on the moist spot. A yellow color indicates the presence of small quantities of phosphates.

BARK should always be removed from timbers before placing them in the mine. There is no economy in placing timbers in any mine, wet or dry, from which the bark has not first been removed. Insects work rapidly between the bark and the wood and a good-sized timber is soon rendered worthless through decay.

*Abstract from U. S. Geological Survey bulletin, by W. C. Phalen.

RECENT PATENTS

1,197,598. CONCENTRATING TABLE. Robert H. Richards, Boston, Mass. Filed May 6, 1913. Serial No 765,915.

1. The combination of a laterally inclined, longitudinally shaking concentrating table adapted to deliver the concentrated product over the end edge thereof; guiding means on the discharge end of said table, extending substantially the entire depth of said end edge to guide the concentrated product during discharge, and a divider structure for receiving material discharged from said guiding means and for maintaining the classification thereof.

1,198,519. METHOD OF TREATING LIQUIDS WITH GASES. Charles S. Bradley, New York, N. Y. Filed Dec. 18, 1913. Serial No. 897,537.

1. The method of producing chemical action between a gas and a liquid, which comprises introducing into the liquid a gas which is chemically active with respect thereto, to produce a foam and discharging only the foam therefrom as the product.

1,198,134. COPPER-REFINING FLASKS. A. Garder, New York, N. Y. Filed Apr. 26, 1916. Serial No. 93,728.

1. In the refining of copper, the flask consisting of a chamber in the center through a cupola furnace, adapted to receive the molten metal, and a series of flaps or partitions adapted to receive the molten metal and to guide the charge in the heat of the furnace, pos-

ing the flapped molten metal over solid carbonaceous material to partially pole the metal, conducting the partially poled metal to a suitable poling furnace, blowing the molten metal in said furnace with air to effect any desired oxidation, and finally blowing the charge with non-oxidizing gas charged with finely divided carbon particles to complete the poling.

1,200,264. ELECTRICALLY-OPERATED HOIST. Fred L. Stone, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Sept. 14, 1914. Serial No. 861,504.

1. The combination with the motor of an electric hoist, of means for gradually varying the speed of said motor between certain points in the travel of the hoist, comprising a controller, a speed responsive device actuating the same to various positions, a second controller actuated by the hoist, and connections between the controllers for effecting the control when the controllers are not in corresponding positions.

1,198,491. DEWATERING AND SCREENING APPARATUS. James B. Ballantine, Silver Plume, Colo., assignor of one-half to William B. Robeson, Port Huron, Mich. Filed Oct. 5, 1915. Serial No. 51,139.

The combination of a crushing means, a hydraulic classifier receiving from the crushing means and adapted to subdivide the material into a series of classes, a draining device adapted to receive the material of the coarsest grade and drain the

same, a draining and screening device adapted to receive an intermediate grade from the classifier and to drain and size the material of said grade, and means for returning the material of the draining device and oversize material from the draining and screening device to the crushing means.

1,200,334. PROCESS FOR THE PRODUCTION OF NITRIC ACID FROM NITROUS GASES. Antonius Foss, Christiania, Norway, assignor to Norsk Hydro-Elektrisk Kvaestowaktieselskab, Christiania, Norway. Filed Feb. 23, 1915. Serial No. 10,071.

1. In the utilization of nitrous gases, the process which comprises absorbing said gases in alkali, decomposing the resulting alkali metal nitrogen compounds by suitable decomposing agents to liberate nitrous acid gas in a more concentrated form, recovering the alkali for the absorption of fresh quantities of gases, and recovering and returning the decomposing agents into the cycle of operations.

1,201,021. FILTERING-BELT. John M. Callow, Salt Lake City, Utah, assignor to The General Engineering Company, Salt Lake City, Utah, a Corporation of Utah. Filed Mar. 4, 1916. Serial No. 82,186.

1. In a filtering machine, the combination with an endless traveling filtering belt and means for separating thereon, the liquid from the solid constituent of a solution to be filtered, of pneumatic devices for removing the caked material from the surface of the belt by exhaustion.

1,201,053. ORE-CONCENTRATING APPARATUS. Thomas A. Janney, Garfield, Utah. Filed Apr. 23, 1914. Serial No. 833,973.

1. In a concentrating apparatus, an agitation vessel and separating box communicating with each other through upper and lower ports, and agitating and impelling means in said vessel for agitating an ore pulp therein and adapted to move all of said pulp from said vessel into said box and to move the pulp in a circuit through one of said ports to said box and back through the other port of said vessel, said box having an overflow lip below the level of said upper port.

1,200,534. PROCESS OF RECOVERING COPPER FROM SOLUTION. George A. Schroter, Denver, Colo., and William C. Laughlin, Nogales, Ariz. Filed Apr. 29, 1915. Serial No. 24,640.

The process of recovering copper from solution which consists in adding calcium hydroxid in solution thereto, filtering same, roasting or calcining the precipitate to render the iron inert, adding sulfuric acid to the precipitate and filtering the copper solution.

1,200,832. APPARATUS FOR EXTRACTING METALS FROM THEIR ORES. John C. Greenway, Warren, Ariz. Filed Mar. 31, 1915. Serial No. 18,289.

1. An apparatus for extracting metal from its ores comprising a series of leaching tanks adapted to contain the ore, a circulating pump for each tank having its inlet and outlet connected to said tank for circulating leaching solution in each tank, means for advancing the solution from each tank to the succeeding tank, means for supplying solution to the first tank of the series, and means for withdrawing solution from the last tank of the series.

1,192,065. CABLE-GRIP. Vilas H. Jackson, Cleveland, Ohio. Filed Nov. 3, 1915. Serial No. 59,413.

1. A cable-grip including a plurality of gripping jaws each having its outer face inclined, opposed relatively slidable elements engaged upon the inclined faces of the jaws, operating connections between said elements, and means connected to said operating connections to actuate the same and simultaneously shift said elements upon the relatively stationary jaws to force the jaws into gripping engagement upon a cable arranged between the same.

1,201,301. PROCESS OF MAKING EMULSION AND PRODUCTS THEREOF. Henry Hicks Hurt, assignor to Robeson Process Company, New York, N. Y. Filed Jan. 27, 1916. Serial No. 74,687.

1. The process of making permanent emulsions of oils and sulfite waste liquor preparations which comprises thoroughly intermingling such a preparation and such an oil and after the mingling is complete adding a small amount of caustic soda.

2. The process of making permanent emulsions of drying oils and sulfite waste liquor preparations which comprises thoroughly intermingling such a preparation and such an oil and after the mingling is complete adding a small amount of caustic soda.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

CRIPPLE CREEK, COLORADO

GOLD YIELD—VINDICATOR FLOTATION PLANT.—DRAINAGE-TUNNEL.

The gold output from the Cripple Creek district for October is reported by the mills and smelters as follows:

	Tons	Average value	Gross value
Golden Cycle, Colorado City	237,000	\$18.00	\$666,000
Portland, Colorado Springs	19,378	20.16	221,316
Portland, Cripple Creek	19,700	2.62	51,614
Smelters—Denver and Pueblo	1,500	55.00	247,500
Isabella mill	2,100	2.90	6,950
Worcester-Ruble mill	1,200	2.50	3,000
Total	275,778	\$15.79	\$1,196,390

The 250-ton flotation plant of the Vindicator Consolidated started operating a week ago. If the results are as satisfactory as anticipated, steps will immediately be taken to enlarge the capacity.

Work in the Roosevelt drainage-tunnel has been temporarily suspended, on account of the shut-down of the Elkton main shaft. Re-timbering of the shaft down to the 200-ft. level is under way, and as soon as this is completed, work will be resumed in the heading of the tunnel.

FLAT RIVER, MISSOURI

CONDITIONS IN THE LEAD DISTRICT—ST. LOUIS COMPANY BUYS LAND—NEW MILL OF FEDERAL LEAD, DOE RUN POWER PLANT—FREDERICKTOWN DISTRICT.

During the past few months this district has prospered under the high price of lead. For a time the market showed a tendency to decline, but about the middle of August quotations became strong and remained so since. All of the companies are operating to full capacity of the boilers, and a record output of lead is being made. There are no indications of labor troubles, the men being satisfied with their wages, which are higher than ever before. The companies are investing in properties and plants. Drilling, both on prospect and development, has been pushed all the summer.

The St. Louis Smelting & Refining Co. has recently bought the 100-acre tract just south of Elkton, consisting of 620 acres, the purchase price was \$165,000. It had already purchased the E. W. Hill tract between Bonne Terre and Deleville, consisting of less than a quarter section, for which was paid \$60,000.

The new mill of the Federal Lead Co. at Elkton, bearing on both sides the machinery, flatter and longer, being in place. The building is a work of art, the first of its kind, being entirely of concrete and steel. Its location was carefully watched with interest at every development of drilling in this district has been utilized in the new plant.

The new power plant of the Doe Run Lead Co. at River View, on the river, is completing, the addition of its 100-hp. Stirling engine, intended to produce power.

The Foster Elvins company, a new corporation, at Flat River, now owning a mine south of Elkton.

The Fredericktown district is prospering on a scale never known at any time since the early days of 1917. The Missouri Lead Co. has taken over the North American property, and is re-modeling the plant, both running and mill, and is expected to be ready to lead this company to make a record output.

TORONTO, ONTARIO

PORCUPINE, KIRKLAND LAKE, AND COBALT NEWS.—WATER-POWER INVESTIGATION.

A party of 25 Canadian and American capitalists, mining engineers, and others, including Gordon Crean, president, and E. A. Snowman, one of the directors of the Davidson mine, Porcupine, left Toronto on October 24 to make an inspection of that property returning on the 29th. The visitors were much impressed with the value and extent of the free gold exposed, the finest of which is seen in an extension of the main vein 400 ft. north of the shaft, where an open-cut has been made 10 ft. deep and 25 ft. wide, which yielded some rich ore. The main shaft is down 315 ft., and the cross-cut on the 300-ft. level is in 60 ft. towards the vein. Much lateral development has been done on the 100 and 200-ft. levels, and a large body of ore has been developed.

At the Dome Lake the Hardinge ball-mill has been installed and operations will shortly be resumed. The capacity of the enlarged mill is 200 tons per day. Underground development has opened some good ore-shoots and some high-grade ore has been broken in the stopes in the 300 and 400-ft. levels. The shaft will be sunk to 700 feet.

The shaft of the Porcupine Crown has reached a depth of 900 ft. on the main vein, at which level the ore is of good grade. Diamond-drilling to pick up parallel veins is being carried on from the 500-ft. level.

The Inspiration, a recently organized company, the property of which adjoins the Hollinger Consolidated, is about to begin diamond-drilling with the object of finding extensions of the Hollinger veins. H. W. Darling has been appointed consulting engineer.

Another important discovery has been made on the Neway, a new vein having been found near the Plenaurum and stripped for 30 feet.

At the McKane property, Kirkland Lake, the vein on the 300-ft. level is proving much wider than at first. The width is now given at 15 ft., the ore assaying \$9.25 per ton. Ore reserves are valued at \$500,000.

The Lake Shore, Kirkland Lake, has installed a 7-drill compressor and other machinery, and will operate with steam power until electricity is obtainable from Cobalt.

The Nipissing has increased its ore reserves by 1,000,000 oz., by opening a remarkably wide shoot on No. 490 vein. This was cut on the level driven from a winze at a depth of 135 ft., and shows 8 in. of high-grade ore. It is stated that there are indications of other good veins in the immediate vicinity. The Nipissing management has closed an important contract for the handling of its by-products, the principal of which is cobalt, for which there is an increased demand in the manufacture of chrome-nickel steel. The financial statement as of October 2, showed cash on hand and bullion to the amount of \$2,228,110, being the best position in the company's history.

At the Crown Reserve a new vein 3 in. wide has been found on the 290-ft. level. It has been driven on for 35 ft., and in places yielded 2000 oz. per ton.

The Foster Elvins have cut several veins on the 1600-ft. level at the lower contact which contains cobalt, nickel, and some silver.

Samplings of the Little Nipissing on behalf of Detroit and Toronto interests, who have leased the property, is stated to

have given satisfactory results. A company will be formed to operate the property.

Cross-cutting from the lower level of the People's has reached the large vein which crosses that property and the Ophir. It is 8 in. wide and somewhat mineralized.

The Calumet & Montana Consolidated has cut a vein in the east drift at the 60-ft. level.

The Belle Ellen of South Lorrain has taken its place in the list of shipping mines. A consignment of 70,059 lb. of ore of good grade was recently dispatched.

Investigations made by the Canadian Department of the Interior indicate the great possibilities existing for water-power development. It is estimated that 17,746,000 hp. is available, not including the northern territories and outlying portions of Quebec and the Yukon. The power so far developed aggregates 1,712,193 hp. of which Ontario has 789,466, Quebec 520,000, and British Columbia 265,345. Eight million horse-power of the available undeveloped water is within the range of present markets, and will be in use within the next 15 years, according to official estimates.

In the first half of the current year the production of nickel in Ontario was 42% greater than for the corresponding period of last year, according to the report of the Ontario Bureau of Mines issued a short time ago. It is probable that the output and value will be greater also during the last half of the year. Early in 1916 the smelting and refining capacity for Ontario ore will be larger, as additions are being made to that in the United States and England, and new plants are in course of erection in Canada.

JARBIDGE, NEVADA

REVIEW OF CURRENT DEVELOPMENT WORK.

It may be said that the conditions in the Jarbidge district during the past summer have been good and developments favorable. In the early spring, the Starlight, a prospect, through the efforts of N. M. Muir and R. N. Hill, was optioned, and development work carried on by W. P. Hammon of San Francisco, under the direction of E. A. Haggott. Later in the summer, through the efforts of N. M. Muir and A. F. Peery, the Flaxie mine and the Jarbidge Gold properties were optioned, and are now under development by the Hanford interests of San Francisco. These two properties adjoin the Starlight on the north. The Hammon people were offered an attractive advance on their holdings on the Starlight by Hanford, which was accepted, and the development of the three properties, under one management, has been proceeding rapidly. The Hanford syndicate also had several smaller prospects in the district under consideration, which it has now dropped, and is concentrating all of the work on the Starlight-Flaxie-Jarbidge Gold group. The work is under the direction of N. M. Muir, formerly of San Francisco. Development on the Starlight consists of three adits: two of these adits, No. 1 and 2, being the upper ones that have encountered the vein, which has been opened for 350 ft. on No. 2 and for 150 ft. on No. 1 adit. Winzes and raises from these two levels have proved a continuity of ore vertically, at present giving a depth of 250 ft. It is understood that this ore will average over \$15 per ton. About 30 men are employed at the Starlight. The Flaxie mine had considerable work done on it by the original owners, the Flaxie Mines Co., and under the present management new development has been vigorously pushed to the north, through No. 1 adit. It is understood that \$12 ore has been opened in the property, and prospects are encouraging. There are 10 men employed. The Jarbidge Gold is in a good situation, adjacent to the Flaxie and Starlight on the south and the Long Hike on the north. A long cross-cut adit is being driven to cut several veins that are supposed to exist in this ground. Ten men are employed. With the Starlight and Flaxie there are 50 men being employed by the Hanford interests, in a very vigorous campaign.

The Long Hike property is generally understood to be of

large possibilities. The mine is developed by four adits, all of which have cut the vein, and showing a shoot some 800 ft. long. A considerable amount of machinery and equipment is being installed by the Long Hike, such as a semi-diesel plant and generator for a central electric plant, to furnish power for electric hoists in the mine, and electric exhaust fans and diamond-drills. A hoist and skip-way is being installed to take material from the creek level to the mine. Some 75 men are employed under the direction of E. A. Austin. The Long Hike interests are also developing the O. K. property on Bourne gulch. Thirty men are at work there. The Long Hike people are also developing the Alpha, adjacent to the O. K., and have been milling the ore from the O. K., that has been taken out in development, with a five-stamp mill on the Alpha. It is understood that the extraction has been fairly satisfactory.

The I. A. Anderson syndicate, of Spokane, Washington, has optioned and started work on several likely prospects, among them the Kiyi, Swasteka, and National groups. J. T. Macauley is superintendent of this work.

The year 1916 has shown a marked revival in the old-new camp of Jarbidge, and there is a population of 600 or 700 people in the district. A vigorous development campaign is anticipated for the winter, and larger things for next summer. Developments have been interesting, owing to the fact that all of the veins are fissures in rhyolite, it being one of the few districts where there has been such a marked continuity of veins in rhyolite. The underlying geological formations are sedimentaries, and two distinct rhyolite flows cover the country for many miles in extent. The vein systems carry in the second or younger rhyolite. Few of the strong ore-bearing veins outcrop on the surface, the only indication of their whereabouts being pinnings in the surface wash—the two exceptions to this being the large quartz outcrop of the Pick and Shovel vein and the Bourne vein. The proving of these veins in depth will be a valuable and interesting addition to geological information as to veins in rhyolite.

SUTTER CREEK, CALIFORNIA

RESUMPTION OF MINING AND MILLING.—OLD EUREKA.

The Mother Lode towns recently affected by the strike are gradually getting back to normal conditions. Teams and trucks carrying timber and supplies to the mines and concentrate from the mills are again on the road. The Bunker Hill mill resumed crushing at half capacity last Wednesday, and the same day the South Eureka mill started 20 of its 80 stamps. The South Eureka had 80 men on its pay-roll the day after the strike was declared off, about half of whom were strike-breakers from outside districts. The force is being increased daily, and it will not be long before the company is employing its usual complement, 250 men. The Bunker Hill men were the first to return to work, 30 returning before the end of the strike and 60 being at work during the week. As an official of that company, expressed it, "we don't know whether our men were on strike or not, for we laid them off a day or two before so as to do repair work in the shaft, and took a number back before the Union allowed its members to return." As the men apply for work, in most instances the companies are taking them back. The Treasure mine has resumed in full force. The Argonaut and Kennedy employees are slower in accepting their old jobs, although those mines are steadily increasing their crews; many of the men still feel that mines paying so well should not have held out against the Union's demands.

The work of unwatering the Old Eureka mine is proceeding most satisfactorily, the 900-ft. station having been reached with a space of clear shaft below, showing that the timbermen will not have to contend with caves for a while, as they did below the 800-ft. level. About 55 men are employed, the majority of whom are engaged in erecting the steel head-frame and making sundry surface improvements.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JENSEN. September yields of the mines on Douglas island were as follows:

	Alaska Mexican	Alaska Treadwell	Alaska United
Stocks of broken ore in mine, decrease or increase, tons, . . .	19,550	11,199	+14,838
Stamps dropping	120	150	300
Days	17.37	29.75	29.54
Ore crushed, tons	10,780	21,791	48,069
Average yield per ton	\$1.53	\$2.19	\$1.80
Gold from all sources	\$16,545	\$54,249	\$86,546
Operating expenses	12,261	31,140	39,312
Profit	1,119	22,567
Construction	3,109	11,781	21,629
Net profit	1,910	10,786
Loss	35,261
Other Income	3,730	11,281	3,730
Value of copper plates	26,035	42,289

During October the Alaska Gold Mines treated 158,000 tons of ore assaying \$1.32 per ton. Returns for the current year are as under:

Month	Tons	Value	Recovery, %
October	158,000	\$1.32	82.49
September	135,760	1.30	82.91
August	169,000	1.38	81.51
July	159,103	1.24	80.64
June	164,800	1.08	79.25
May	175,215	1.40	82.85
April	165,939	0.94	78.71
March	162,796	1.03	77.47
February	122,858	1.02
January	114,183	1.12

KENNICOLL. The October copper output of the Bonanza mine was 7,300,000 lb., compared with 8,000,000 in September, and an average of over 10,000,000 for the previous 10 months.

REPRODUCED FROM MAP OF YUKON TERRITORY, ALASKA, SHOWING POSITIONS OF KEY TOWNS.

NOVEMBER. The Alsea Mines Corporation has purchased through the Yuba Construction Company of California the largest bucket line ever made. This contract has been given to the Taylor-Wenton Company of Honolulu, N. O. to erect and install the bucket line and related equipment. It is to be made of man-

ganese steel, and installed on the new dredge which will dig 60 ft. below water. This dredge is working on one of the other properties of the company at Nome.

ARIZONA

On November 14 the third annual mine-rescue and first-aid contest was held at Phoenix. Competitors were the Old Dominion, Detroit, Copper Queen, Calumet & Arizona, and Ray Consolidated teams. The prizes are \$100, \$75, and \$25 cash for three places in each of the two contests. The Southwestern Mine Safety Association is in charge of the meeting, J. T. Moore, secretary. Bulletin No. 38 of the State Bureau of Mines is entitled 'State Safety News.'

CHINO. The electric transmission-line reached this place on the 5th. A transformer-station is now being built.

The Elkhart mine has been taken over by W. L. Leland and San Francisco people. A shaft is to be sunk 1000 ft., and the mill re-modeled.

There has been a large influx of people to Chloride, making accommodation difficult to secure. Many buildings are being erected.

HAYDEN. Considerable development is under way at the Gila Canyon Consolidated, 4 miles north. Returns are improving, the last car of ore averaging 6.53% copper, netting \$20.28 per ton.

JEROME. Accommodation here is said to be at a premium, owing to the number of people being attracted by the boom.

The United Verde Extension company states that eight raises have holed through to the 1300-ft. level from that at 1400 ft., and between these levels there is 700,000 tons of ore. The average is 16% copper. Over 300 ft. of drifts have been driven at 1300 ft. A winze below 1400 ft., after passing through 114 ft. of 15% ore and 46 ft. of low-grade ore, encountered at 160 ft., one of the bars of intrusive waste characteristic of the deposit. Sinking continues. On November 1 a dividend of 50c. per share was paid.

MIAMI. Just over 500,000 tons of ore was hoisted by the Inspiration during October, one day's output being 21,300 tons. Additional motors were installed in the crushing-plant. Owing to an armature burning-out in one of the motors of the generator set, control is by hand, instead of the automatic arrangement. This trouble has since been remedied.

OVAN. It is rumored that the Tom Reed company is to erect a 500-ton mill, in place of its present plant.

ARKANSAS

Zinc ore production, mostly calamine, of the northern part of the State in October was 90 carloads.

FORT SMITH. Another zinc smelter, of 2400 retorts, costing \$200,000 is to be erected by the Athletic Smelting Co., headed by C. T. Orr of Webb City, Missouri. The United Iron Works Co. of Springfield, Missouri, is to construct the plant.

CALIFORNIA

BARNWELL. W. B. Sharps of Philadelphia and W. W. Wishon of Searchlight, Nevada, have bonded the Copper King group of mine claims near here, of G. H. Hamstadt, for Eastern interest, and have four men assisting them in making the examination.

(Special Correspondence.) The large gold dredge on Coffee creek is nearing completion. It is reported that another boat

will be constructed next year by the same company on Graves ranch, two miles south of Carrville.—It is reported that the company which bought out the Alta Bert Gold Dredging Co. at Trinity Center, four miles south of Carrville, will construct a large boat next year.—The Nash deep-gravel mine at the head of Coffee creek, for many years owned by an English company, was recently sold for \$10,000 to a San Francisco man.—Atkins, Kroll & Co. of San Francisco have lately taken a bond on a hydraulic mine owned by Williams & Carter, situated on the north fork of Coffee creek. It is reported that the same firm, present owners of the Headlight mine, will try a new process in the spring. The mine has been shut-down for four years.—The Strode mine has been under bond for some time for \$15,000. Considerable ore was milled this season. A contract has been let for a 750-ft. adit. The same concern that has the Strode mine under bond has a bond on the Schlomberg hydraulic mine on the north fork of Coffee creek.—The Bonanza King mine has been doing a great deal of development during the past two years.—The Jubilee mine on Coffee creek, owned by McCormack, Saezter Co. of Redding, and under bond to the California Extraction Co. of San Francisco, is doing a large amount of development. The vein was recently cut in a lower adit. The Porth mine, an adjoining property owned by the same company, will do some development this winter.—There is considerable work under way up in Scott mountain, north of here, just over the Siskiyou line.

Coffee, Trinity county, November 4.

(Special Correspondence).—The latest discovery of importance at Goldstone, the new district 30 miles north of Barstow, in San Bernardino county, is in the Gold Ring mine, where high-grade ore is reported found in a four-foot vein. The 22-in. pay-streak is in the centre of the vein, with a rich strip four to six inches wide in the middle of it. The vein-material is quartz and calcite with iron oxide. The gold-bearing formations as far as explored are old sediments, probably Paleozoic, much metamorphosed. The principal rocks are limestone and quartz-schist, intruded by dikes of various character. These sediments have been tilted by uplift and dip from 20 to 70°, with pronounced fracturing and shearing. By faulting, the underlying granitic rocks have been brought to the surface along the edge of the district and these now form some of the higher hills of the vicinity. The sediments dip toward the granite and abut against it, thus indicating at least one fault of large displacement. Tertiary volcanics are found capping many of the outlying hills of the district. All of the gold-bearing veins thus far found in the camp occur in the metamorphic area, and usually at the contact of limestone with some other rock.

Goldstone, November 9.

GRASS VALLEY. Three miles of the bed of Greenhorn creek has been leased by W. H. Frickleton to L. Girdetz, who will install plant to recover the gold.

HAMMONTON. On November 20 the Yuba Consolidated will launch No. 15 dredge, one of the largest in the world.

HAPPY CAMP. The Williams Brothers' copper claims on Buzzard creek, Siskiyou county, have been bonded for \$50,000 to M. Woods of the Bank of Italy.

KENNETT. Large quantities of material are arriving for the Mammoth Copper Co.'s electrolytic-zinc plant. Construction is making good progress.

PORTOLA. It is probable that a railway will be constructed from this place into the Walker district. Either the Western Pacific or Feather River Lumber companies may extend their lines. The Walker copper mine is employing 150 men, while the mill treats 100 tons daily.

SONORA. According to the *Union Democrat*, the revival of interest in mining in Tuolumne county has been largely confined to new operations on the Mother Lode for the past two years, practically to the neglect of that highly-mineralized sec-

tion known as the 'east belt,' whose veins in the past have a producing record equal to some of the large mines on the Mother Lode. Miners and investors are now turning to this inviting field, and already in many instances limited exploration work has demonstrated that while the early miners recovered much gold from the quartz claims, many of them were abandoned before really opened, and none of them were ever worked out. In a number of these claims work has been commenced and is being pushed in a manner that makes for success. In the Columbus mine, operations are confined to driving the shaft down to the 500-ft. point. A grade of ore uncovered in development gives a value of \$10 per ton. The Carlotta, in the same vicinity, is showing some good ore. Adjoining are the North Star and Laura claims, and operations are under way in the former. The Sonora and Duffield, south of the Dreisam, is being re-opened for examination. This mine has a small vein, but it is rich in free gold and yields about 2% of high-grade sulphides. The Confidence mine is to be re-opened by a strong company, and other properties in that vicinity are being negotiated for under bond to purchase. When the legal entanglements have been straightened out in the United Mines Co. group of five claims plans for operations on a gigantic scale will be put in execution. The Chapparel mine and the Garfield group are held under option, and other properties here and there along the east belt and side-lines are receiving considerable attention, and before many months the 'music' of stamps will be continuous all about the hills within a radius of half a dozen miles of Tuolumne.

COLORADO

TELLURIDE. In the last *Quarterly* of the Colorado School of Mines, W. H. Wright details experiments on Colorado ores by flotation. A complex sulphide ore from the Smuggler-Union

PART OF COLORADO.

mine was chosen for large tests. It contained 0.36 oz. gold, 4.04 oz. silver, 1.87% lead, 5.99% iron, 1.59% zinc, a trace of copper, and 78.6% of insoluble matter. The last was principally quartz. The results are not yet complete, but so far are interesting. An extraction on one lot was 82.1% gold, 84.4% silver, 86.7% lead, 62.8% iron, and 74.2% zinc.

In an article published in the Colorado School of Mines *Quarterly*, R. W. Shumway, chief engineer of the Rocky Mountain Fuel Co., discusses the coal industry of the State. He considers that it is one of the largest factors in the business of the State, as its scope is broad and its field of operations covers nearly half of the counties of the State. One town, among others, Trinidad, with 12,000 people, depends entirely on coal. The output in 1915 was 8,715,397 tons. Colorado

produces practically all the grades of commercial coal used in the West. There are large areas of undeveloped coal, due to lack of markets.

LEADVILLE. Two carloads of high-grade iron-manganese ore has been shipped from the Penrose shaft of the Down Town Mines to the A. S. & R. smelter at Denver. This is the first ore production since the property was drained. A steady output is contemplated. The pumps are lifting 2500 gal. per minute.

SILVERTON. The Buffalo Boy, Ben Franklin, and other properties in this district have been examined by the Goldfield Consolidated Exploration Company.

IDAHO

Idaho's 33 counties cover an area of 82,888 square miles, divided principally between the Rocky Mountain region and the Columbia plateau, only a small part, in the south-east corner of the State, lying in the Great Basin. In elevation above sea-level the State ranges from 735 ft. at Lewiston, to 12,078 ft. at the summit of Hyndman peak. It is drained mainly to the Columbia through Snake river and its tributaries and has an annual rainfall of about 17 in., the range in a single year at different places being from 6 to 38 in. The industries of the State are chiefly agriculture, stock-raising, and mining. Hay, wheat, oats, and potatoes are the principal crops. A large area is cultivated by irrigation. The mineral production includes gold, silver, copper, lead, and zinc. The output of lead in 1913 was valued at \$13,986,366, that of silver at \$6,033,473. The population of Idaho in 1910 was 325,921. These are notes from the Overland Guide-book, Bulletin 612, U. S. Geological Survey.

CAMAS. Reports from the Salmon River district point to a busy season next year. The old Warrens camp has been more active.

MULLAN. Plans for the resumption of active operations at the Missoula copper mine were considered at the annual shareholders' meeting at Mullan on November 6. The property is extensively developed, and engineers' reports state that there are thousands of tons of ore available for extraction that will assay 1 to 2½% copper, and at prevailing prices of the metal it is believed that ore averaging even as low as 1% can be mined and shipped profitably.

NIMMIE. According to D. F. Bailey, consulting engineer for the Interstate Callahan company, the mine never was in better physical condition, and the outlook for further profitable development is decidedly promising. Drifts have been extended 300 ft. on both levels above No. 1, the main haulage-level and are still in ore. The addition of 300 ft. exposes the body for 1000 ft. In all, whereas the engineers had calculated on only 700 ft. Conditions suggest that the shoot may prove to be as long as on the lower levels, where it has been followed for 1300 ft. It is 7 to 15 ft. wide, and 18 ft. wide in places on the upper levels. One cut recently on the 700-ft. level, where the depth is 1600 ft., has been driven on for 100 ft. It is 7 to 20 ft. wide, and its average quality is as good as the rest of the mine. The mill feed has been 2½% zinc and 6% lead for the last 18 months. On the 500-ft. level, which is 125 ft. above No. 7, there have been installed 13 chutes, and one is in the face of the drifts. This provides a continuous rope 1300 ft. long in the richest ore exposed at any time. Plans and the organization have been completed for the flotation plant the construction of which will occupy two or three months. Impounded tailing will be removed from the dump to the plant by a continuous automatic drag. The expense of handling by this method is \$ to 10c. per ton in other places. The tailing will be ground in a tubemill, and passed on to the flotation section. There is 250,000 tons that range in content from 1 to 7%, and 1% can be treated at a profit. When the flotation plant is in operation a recovery of from 93 to 95% of the ore is expected, and an increase in the saving of lead. Operations

have been started on the Nipsic mine, where are expected some developments of importance.

WARDNER. The Stewart Mining Co. is negotiating for properties adjoining the Stewart mine, and also is seeking the right, under lease, to develop and extract ore beneath the streets and alleys of Wardner and under private property in the town. The lease is to run for 25 years, under payment of 5% of the gross proceeds from the sale of ore removed. The mayor, B. Flaig, and the board of aldermen have signed the lease for the city, and practically all the owners of private property have signed. The leases are made in the name of William A. Beaudry, managing director of the Stewart company, and his activities in this regard have caused considerable speculation.

MISSOURI

JOLIET. The ore market was strongest last week, blende increasing \$4.50 per ton to \$80. The output of the Missouri-Kansas-Oklahoma region was 6175 tons of blende, 250 tons of calamine, and 676 tons of lead, averaging \$77, \$43, and \$87 per ton, respectively. The total value was \$515,321.

MONTANA

BUTTE. For the sum of \$673,717, the minimum stipulated by the Court, the Anaconda company last week purchased the Lexington and other claims in the Walkerville district. The properties once belonged to La France Copper Co., a Heinze concern, and later to the Atlantic Mines Company.

The Anaconda company's October pay-roll amounted to \$1,672,264, a record. The wage is \$4.50 per shift.

During October the Butte & Superior produced 15,600,000 lb. of zinc from 54,450 tons of ore.

NEVADA

EUREKA. The recent rich discoveries in this old centre keep up their value in gold, silver, and lead.

TONOPAH. During the week ended November 4, eight mines produced 10,176 tons of ore valued at \$199,108. In the next week the output was 9757 tons worth \$191,566.—The Tonopah Mining Co. is averaging about 290 ft. of new openings each week, distributed in its three mines.—The Victor shaft of the Extension is 1685 ft. deep.—Two diamond and one churn-drill are prospecting new property of the Belmont.—A raise above the 1025-ft. level of the Monarch Pittsburg has opened 1 ft. of \$30 ore. The shoot has been opened for 23 feet.

NEW MEXICO

(Special Correspondence.)—At the Pacific mine the haulage-cable for the aerial tram to the Socorro company's mill was placed during the week, and the traction cable is now being installed. A good vein has been encountered in north drifts from the 500 and 600-ft. levels. The territory south of the shaft will be opened later, as present underground activities are up to the limit of hoisting equipment.

The new shaft at the Johnson mine, operated by the Socorro M. & M. Co., is down 255 ft., still in a milling grade of ore.

Ore is coming in on the south drift from the adit-level of the Clifton mine, on which the Oaks Company is conducting development work.

The slime-carrying flume being built by the Mogollon Mines Co. has been completed from the Last Chance mine to the Maud S property, a distance of about one mile, and is now in commission. This will eventually be extended about 4 miles farther down the canyon on to the present tailing impounding dams.

There are practically no idle men here, and from different quarters comes the report of a scarcity of labor of all classes to a greater extent than has been noticed for some time past.

Mogollon, October 31.

OKLAHOMA

CARDIN. W. H. Langford and associates of Kansas City and W. J. Scafe of Joplin are drilling and developing five tracts near this place, aggregating a total of 320 acres. One lot that involves a good portion of the townsite of Cardin promises to develop into one of the best properties in this part of the Oklahoma field. Twenty-four drill holes already were down, all showing some ore, but in twelve of them an unusually rich run at from the 200-ft. level down to 242 ft., and also from 220 to 245 ft. In some places the ore runs deeper than in other parts of the lease. Five or six drills are at work putting down holes as fast as possible.

UTAH

AMERICAN FORK. During the winter 18 mines will be operated. By the middle of November the Utah Power & Light Co. will have its transmission-line completed into the district.

GARFIELD. Preliminary work for the construction of a plant to treat the tailing from its mills has been started by the Utah Copper Co. The dams contain 50,000,000 tons of residue containing about 10 lb. of copper per ton.

GOLD HILL. To get its rich tungsten ore to market the Seminole Copper Co., operating in the Clifton district of the Deep Creek region, western Tooele county, has for some time been shipping by parcel post at a cost of \$26.50 per ton. The dumps contain 10,000 tons of concentrating ore.

PARK CITY. The new aerial tram at the Silver King Consolidated, 10,200 ft. long, is working well, delivering ore to the sampler and mill.

The Broadwater Mills Co., which is treating tailing near Park City, is to re-model its plant.

Good progress is reported on construction of the Judge M. & S. Co.'s electric zinc smelter.

TINTIC. In the report of Walter Fitch, general manager of the Chief Consolidated Mining Co., it is stated that during the period January 1 to September 30, development covered 17,950 ft. Ore shipments totaled 62,006 tons, assaying 0.104 oz. per ton gold, 21.37 oz. silver, 13.08% lead (on lead ore), 1.95% copper (on copper ore), and 30.5% zinc (on zinc ore), an average value of \$31.38 per ton. The net profit was \$474,247. Development was extremely satisfactory. Dividends totaled \$132,331. On October 1 the cash balance was \$446,970.

WASHINGTON

REPUBLIC. The Lone Pine-Surprise Mining Co. is preparing to begin sinking a 500-ft. shaft on its Last Chance claim at Republic. A 5-drill compressor, hoist, and a 100-hp. boiler have been ordered.

SPOKANE. The Coeur d'Alene Mine Owners' Association, of which Stanley A. Easton, general manager of the Bunker Hill & Sullivan Mining Co., is secretary, will install a comprehensive display of the minerals of the northern Idaho region in the new quarter at the Spokane hotel of the Northwestern Mining Men's Association, a re-organization of the Spokane Mining Men's club, the pioneer society in the Northwest of men interested in the mining industry.

CANADA

BRITISH COLUMBIA

SILVERTON. During September the Standard Silver-Lead company made a profit of \$38,287. The monthly dividend of \$50,000 was paid. On October 1 the balance was \$254,319. Revenue from lead and zinc products, etc., totaled \$60,176. Ore production, including mining, shipping, marketing, taxes, etc., amounted to \$36,288. In July the profit was \$56,608, \$30,398 in June, and \$136,943 in March.

TRAIL. For the 10 months of 1916 the smelter at Trail has received 415,143 tons of ore, against 399,070 tons in this period of 1915. New producers in the Slocan district are the Revenue and Sovereign; and the Johnson at Merrett.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

H. H. CLAUDET is in Ontario.

JOHN BAILLOT is at Washington.

G. W. EVANS has returned to Seattle from Alaska.

F. LYNWOOD GARRISON has returned to Philadelphia from Brazil.

THEODORE J. HOOVER has arrived at Palo Alto from New York.

A. W. ALLEN, recently with the San Juan Mines, in Argentina, is here.

H. J. SHAFER has returned to San Francisco from Dulzura, on the Mexican border.

VICTOR C. ALDERSON was in San Francisco last week, on his return from New York.

GEORGE CRICAR passed through San Francisco on his way from Spokane to Los Angeles.

EDGAR A. COLLINS is in San Francisco, the Oceanic quick-silver mine having been shut-down.

E. GYBSON SPILSBURY has gone to Cuba, and will be away from New York for about three weeks.

WILLIAM C. MADGE is in San Francisco on his return from Siberia. He will proceed to London shortly.

M. M. VALERIUS and V. H. McNUTT of Tulsa, Oklahoma, have returned from a six weeks' business trip to New York.

E. V. DAVELER, superintendent of the metallurgical department of the Alaska Gold Mines Co., is at the Palace hotel.

H. G. THIELE has resigned as assistant editor of the PRESS and has gone to Glacier, Washington, to superintend erection of a cyanide-flotation plant.

DORSEY A. LYON has returned to Salt Lake City from Washington and New York, where he has been studying operations at electro-metallurgical plants.

PAUL KRUGER, master mechanic at the Inspiration mine, leaves at the end of the month to take a position at the property of the Chile Copper Co., at Chuquicamata, Chile.

NORMAN L. WYBROD, until November 1 in charge of the powdered-coal department of the Anaconda Copper company, has become identified with the Powdered Coal Engineering & Equipment Co. of Chicago.

C. E. MILLS, general manager of the Inspiration Consolidated Copper Co., has been chosen president of the Cananea Consolidated Copper Co., succeeding L. D. RICKETTS, who retires from the office to devote his attention in a general and advisory capacity to the affairs of both these companies in New York, where he has maintained an office for the past two years.

EDGAR TAYLOR has been elected president of the Institution of Mining & Metallurgy, London, in place of Sir RICHARD REDDAINE, who felt compelled to resign owing to his position in the service of the British Government at a time when the Institution was engaged in questions affecting the taxation of mines. Mr. Taylor was President for two terms between 1906 and 1910.

The sixth annual meeting of the members of the Columbia section, A. I. M. E., will be held at the Spokane hotel, Spokane, Wash., Nov. 25. There will be a discussion on United States mining laws, flotation, land classification, State and national co-operation, etc. It is hoped every member of the section will be present and prepared to discuss any of the above subjects, or any other. Bring in an application. Advise the secretary of your present address. The nominating committee desires each member to select officers of his own choice if those named are not acceptable for any reason.

THE METAL MARKET

METAL PRICES

San Francisco, November 14

Antimony, cents per pound	12.50
Electrolytic copper, cents per pound	32.50
Pig lead, cents per pound	12.25-8.50
Platinum, soft and hard metal, per ounce	105-111
Quicksilver, per flask of 75 lb.	\$80
Spelter, cents per pound	13
Tin, cents per pound	43
Zinc dust, cents per pound	20

ORE PRICES

San Francisco, November 14

Antimony, 50% metal, per unit	\$1.25
Chromite, 40% and over, each car California, per ton	15.00
Magnetite, crude, per ton	8.00
Manganese, 50% under 35% metal not desolved	16.00
Tungsten, 60% WO ₃ per unit	17.00

At Boulder, Colorado, last week, 14 tons of tungsten concentrate was sold for over \$15 per unit. The Primos company has advanced prices to its lessees.

New York, November 8

Antimony. Considerable inquiry is reported, and \$1.50 per unit has been paid for small quantities of high-grade material.

Molybdenite. This mineral continues difficult to obtain. Quotations are unchanged at \$1.70 to \$1.80 per lb. of MoS₂.

Tungsten. For small lots of ore \$17 per unit has been paid for prompt delivery. There is active inquiry for ore contracts.

EASTERN METAL MARKET

(By wire from New York)

November 14. Prompt copper is scarce; there is an active export and domestic demand; quotations are nominal for first quarter, lead is dull, spelter is fairly active, advance in ore strengthens.

SILVER

Below are given the average New York quotations, in cents per ounce of fine silver:

Date	1914	1915	1916	Average week ending
Nov. 8	11.67	11.67	11.67	69.12
" 9	11.84	11.84	11.84	67.82
" 10	11.84	11.84	11.84	67.82
" 11	11.84	11.84	11.84	67.70
" 12 Sunday	11.84	11.84	11.84	67.70
" 13	11.84	11.84	11.84	67.52
" 14	11.84	11.84	11.84	71.68

MONTHLY AVERAGES

Date	1914	1915	1916	1914	1915	1916
Jan.	37.78	48.85	6.06	34.90	47.52	63.06

June	38.41	49.02	6.11	35.11	48.88	67.86

The past week has witnessed a sharp drop in silver, with the new high price remaining fairly steady. London reports that America has been selling freely, but has been showing little interest, and China a large quantity of goods. Stocks at Shanghai remain fairly constant at 1,000,000 and 1,500,000 in Mexico in dollars.

The merchant silver market is active, and silver valued at \$10.00 per ounce for export and for use.

Silver bullion, imported from Europe, is now valued at \$12.236.

COPPER

Prices of electrolytic copper, in cents per pound:

Date	1914	1915	1916	Average week ending

June	11.41	13.49	13.99	11.41	13.99	13.66

Export of copper during last week, 11,250 lb. compared with 11,750 lb. the previous week.

amounted to 135,541,187 lb. compared with 34,442,615 lb. Imports of copper were 326,448,620 lb. against 196,281,944 pounds.

Twenty-five mines in North and South America produced a total of 1,841,159,718 lb. of copper in the first 9 months of this year.

Anacosta produced 31,500,000 lb. in October; Shannon, 757,000; East Butte, 1,650,000; Inspiration, 11,300,000; Chile Copper, 1,542,000; Kennecott, 7,200,000; Shattuck, 1,663,671; and Arizona Copper, 1,900,000 pounds.

Champion, Michigan, has declared \$6.40 per share, making \$19.80 for the year. Anacosta is now producing copper at the rate of 1,000,000 lb. daily.

LEAD

Lead is quoted in cents per pound, New York delivery.

American Zinc, Lead & Smelting Co.'s profits for the third quarter of 1916 were \$1,713,000, plus \$725,000 from its Granby properties.

During the third quarter of 1916 the New Jersey Zinc Co.'s net profit was \$8,189,511, of which \$6,650,000 was paid in dividends.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds.

TIN IN AMERICA

As of Nov. 15, 1916, the tin smelter at Perth Amboy, designed to produce 2,000 tons of metal monthly, is only yielding 300 tons. The output is to be doubled.

Eastern Metal Market

New York, November 8.

Copper producers are sold-up well into next year. Millions of pounds have been purchased at advancing prices in the past 10 days, and deliveries in the remainder of this year can only be had at premium prices. Only one thing could impair the future of the metal—a failure to consume the copper already purchased, and this is unlikely, considering that the brass and copper mills continue to be offered business that they cannot handle.

Though it has quieted down considerably, zinc had an active period, both galvanizers and brass mills buying freely. Dealers have sought to acquire stocks on a rising market.

Lead has been quiet in every direction, but prices have been well maintained.

In tin the week has been quiet, but prices are a little stronger.

Antimony, except for one good transaction, has continued dull. Asiatic grades are quoted at 12.75 to 13.25c, duty paid.

Aluminum prices are a trifle easier at 63 to 65 cents.

The pig-iron trade faces a run-away market. It is excited, and even at higher quotations the producers are reluctant to sell, feeling that still higher prices will yet prevail. Coke is equally excited, prompt foundry coke being up to \$9.50 per net ton at oven. Prompt furnace is quoted up to \$7.75 per ton. Eastern Pennsylvania No. 2X foundry iron is quoted at \$25 to \$27.50, delivered. Basic has sold at \$25 to \$25.50, delivered. Standard low-phosphorus iron is quoted in the East at \$43 to \$45 per ton, delivered. Western prices are commensurate. The production of pig iron in October broke all records, the month's production being 3,508,849 tons, or 113,189 tons per day, against 3,202,366 tons in the 30 days of September, or 106,745 tons per day. The October output represents a yearly output of 41,700,000 tons. The pressure on the steel mills, for plates, shapes and bars, is so great that some of them are refusing to quote for next year, except to cover contracts which the prospective buyers actually have in hand. Railroad-car builders are eager to cover their requirements at present prices, having abandoned hope of lower quotations. In the past three weeks the railroads have placed orders for at least 30,000 cars. The leading producer of steel and its products quotes 3.25c, Pittsburg, on tank plates, 2.80c, Pittsburg, on structural shapes, and 2.70c, Pittsburg, on bars; but these are nominal prices, inasmuch as deliveries made on them are indefinite. Specified deliveries are commanding 4c, or more for plates, 2.85 to 3c, for shapes and 2.85c, (all Pittsburg) for bars. An Eastern mill has advanced its plate price to 4.75c, Pittsburg base.

COPPER

The aggregate of sales in the past few days is large, some estimates placing the amount of electrolytic taken by consumers in the first six days of the month at 75,000,000 lb. Metal for delivery over the remainder of this year, and even in the first quarter of next, is scarce, and it is more than likely that extremely high premiums will be asked for prompt from this time on. Most of the buying called for first-quarter deliveries, although considerable November and December was wanted also. Large as recent sales have been, they undoubtedly would have been larger had the copper been available for the desired deliveries. The brass mills have been large purchasers. In a few cases sales have been made over the first half, and in one instance a sale is reported for delivery throughout the coming year. Quotations for nearby deliveries are covering a wider spread than usual, and with actual prices mostly a matter for private negotiation, it is difficult to closely gauge the market. Prompt and November is conservatively held at 29 to 29.50c, although a sale of spot

metal is reported at 31c. For shipment throughout 1917 a large block was sold at 26.75c. December is quoted at about 29c., January at 28.50c., February at 28.25c., and March at 28c. Getting copper nearer than March is a difficult matter. Lake is more easy to obtain than electrolytic, especially arsenical brands. A large quantity of the latter was sold last week for March delivery at 28c. Prime Lake is priced about the same, or a little lower, than electrolytic. On Monday, November 6, the day preceding the election, the market was active here, and excited in London, the latter advancing £1 10s. to £144. Foreign stocks showed but little change according to the last fortnightly statement. Total stocks in Great Britain and France, October 31, amounted to 5458 tons, against 5796 tons, September 30. Total stocks in those countries, combined with those afloat from Chile and Australia, amounted to 19,168 tons, October 31, against 19,371 tons a month previous. Imports of copper were large in the first nine months of this year, amounting to 156,000 tons, against 137,500 tons in the entire year 1915. These imports include, ores, matte and regulus reduced to fine copper. Students of the War predict that it will last at least two years longer and, needless to say, as long as it lasts, copper will be scarce and prices strong.

ZINC

In keeping with the movement in copper zinc has been active, although the demand now appears to be easing off. Producers are optimistic, and have such faith in the future of prices that they are not willing to sell freely. Dealers, on the other hand, are anxious to buy, and it should not be forgotten that they make their living to a considerable extent in accurately forecasting market conditions. Brass mills and galvanizers both were active last week. The New York quotation, November 6, yesterday, election day, being a holiday, was about 10.75c, and that at St. Louis 10.50c. December is held at 10.37½c, and upward. St. Louis, and first quarter at 10.25c. St. Louis. Exports in the first six days of the month totaled 2861 tons. The spot quotation at London on the 6th was £53 5s., against £52 15s. a week previous. Sheet zinc is quoted at 16c., f.o.b. mill, carload lots, 8c. off for cash.

LEAD

The market has been quiet, but steady, and almost entirely devoid of feature in the past week. The A. S. & R. Co. continues to quote 7c., New York, and 6.92½c., St. Louis. The independents also quote 7c., New York, but are willing to make a slight concession for delivery to Eastern points. At St. Louis the smaller producers ask about 6.87½c. The exports of six days of this month total 678 tons. The London quotation for spot, on the 6th, was £30 10s., which was the quotation of a week previous.

TIN

In this metal the week has been a quiet one, but, nevertheless, an advance in price is shown. Spot Straits was quoted on November 6 at 42.75c, and spot Banca at 41.75c. On the 3rd the market was interested, but not excited, by the news that the steamer *Glenbanan*, with about 350 tons of tin aboard had been sunk in the Mediterranean by a submarine. Ordinarily such news makes the market jump, but this time consumers were mildly indifferent. Perhaps it was because they have been fooled so many times. The supply of spot Banca tin was nearly cleaned-up lately, but more Banca will be available as offerings of future shipments from Batavia are now being made. Arrivals this month total 295 tons, and there is afloat 1377 tons. In September, 88,222 lb of tin, valued at \$45,394, was imported at San Francisco and 1,445,234 lb., valued at \$552,485, was imported in the Washington district.

Company Reports

ROUND MOUNTAIN MINING CO.

In the report of the president, L. D. Gordon, and superintendent, R. H. Ernest, of this company operating a mine, mill, and gravel deposit in Nye county, Nevada, the placer operations are discussed. Results this season, up to July 1, were somewhat disappointing, both in yardage and value. Water was also lacking. Churn-drilling and blasting ahead of the glants is being done, and other improvements to methods applied. From July 13 to September 3, 1915, there was sluiced 18,150 cu. yd. of gravel, yielding \$2,006 per yard, at a cost of 60.9c. Irregular work from November 1915 to March 1, 1916, recovered \$1,746 per yard from 5272 yd., costing \$1,023 per yard. Several difficulties tended toward this latter high cost. From March 1 to July 1, 1916, 112,600 cu. yd. yielded 33.8c, at a cost of 19.5c per yard. The gross yield for these four months was \$18,177, but the bed-rock and sluices are estimated to contain between \$20,000 and \$30,000, making, say, 50c per yard for the lot.

Original estimates of the value of the placer deposit, \$1 per yard, were based on previous hydraulic mining and sampling, the former work yielding \$1.55 per yard. Topography of the ground, a ridge under the gravel, probably has caused a variation in the gold-content, and this condition was not found out in time to cut new races into richer ground. Pan tests indicate an improvement to the north, and the influence of the ridge is diminishing as the new cut is carried easterly. The remainder of the season should yield highly-profitable ground.

The main tailing-dump is to be extended to another block of ground, and line it with steel rails. Wood blocks and boulders delayed work during the season. Costs are expected to be lowered to 15c per yard.

GRANBY CONSOLIDATED MINING, SMELTING & POWER CO.

Operations of this company in British Columbia show expansion in each annual report, that for the year ended June 30, 1916, being no exception. In the reports of the managing director, F. M. Sylvester, superintendent of mines, O. B. Smith; mine superintendents, C. M. Campbell and E. E. Campbell; superintendent of smelters, W. A. Williams; and smelter superintendents A. J. Bone and W. B. Bishop, the following details are given:

At Phoenix the Knob-Hill Ironside mine produced 760,693 tons of ore averaging 0.95% copper from the Victoria shaft, and 193,206 tons from No. 2 tunnel, containing 1% metal. The cost on cars was 82c and \$1.10 per ton, respectively. Reserves total 3,530,296 tons of regular grade, compared with 1,171,005 tons at the beginning of the year. The Gold Drop mine yielded 112,100 tons of 0.95% ore, at a cost of \$1.32 per ton. This mine was considered depleted, but diamond-drilling has found 100,000 tons additional ore, which can be mined for \$1.40 per ton. Development at this group of mines totaled 11,608 ft., costing 15 1/2c per ton; also 11,392 ft. of drilling. The average cost was 9 1/2c per ton crushed on cars.

At Hidden Creek underground work totaled 2333 ft., also 5873 ft. of drilling. Reserves in the four orebodies total 18,018,020 tons, over half of which is high-grade material. The mine produced 725,821 tons, at a cost of 39.6c per ton on cars, including all charges. The haulage-system is being improved. The crusher averaged 296.2 tons per hour during the year, that is, 1537 hours of operation, or say 90 hours daily. The new crushing-plant was completed in January. Cold weather affected the power supply. Diamond drilling using hollow steel superspeed large piston drills, to advantage. There was some unrest among employees, but this was settled.

The output from all mines was 1,889,253 tons, averaging

28.13 lb. copper, and 63c. in gold and silver per ton. The mines contain over 23,000,000 tons of ore developed, and are equipped and ready to produce 4000 to 5000 tons daily. Of 2 to 2 1/2% ore there is 9,947,000 tons, of 1 to 1 1/2%, 3,718,000 tons, and less than 1%, 9,491,000 tons.

At Grand Forks, 7.27 furnaces reduced 1,166,015 tons of ore, matte, converter slag, and flue-dust, at a cost of \$1.237 per ton, an increase of 5c. per ton. Coke consumed was 13.42% of the charge of ore. Including 4,801,355 lb. of copper in Anxoy matte, the output was 15,989,730 lb. Converting cost 6c. per ton. Slag contained 4.2 lb. per ton.

An average of 3.2 furnaces at Anxoy reduced \$22,919 tons of ore, and a total of 1,103,825 tons of all materials. Smelting and converting cost \$1.804 per ton of ore. Hidden Creek ore was more silicious and aluminous than before. Double smelting was tried with success. There were 278 men employed.

Summarizing, the year's results were as follows:

Ore treated from company's mines, tons.....	1,897,251
Recovery, pounds of copper	22.36
Total copper, pounds	42,198,083
Silver, ounces	487,845
Gold, ounces	44,848
Revenue from metals sold (copper averaging 22.04c.)	\$10,482,709
Cost, cents per pound	12.98
Profit	\$3,819,295
Dividends	\$99,911
Surplus	\$2,919,384

Cash and metals on hand amount to \$2,927,317, and accounts payable \$281,597. The company treated 31,954 tons of custom ore, yielding 3,356,570 lb. copper, 41,346 oz. silver, and 2100 oz. of gold.

LAKE VIEW AND OROYA EXPLORATION

This is a holding company, having interests in mines throughout the world. In the report dated October 13, 1916, it is stated that the profit was \$12,971, plus the previous balance and reserve account income, making \$42,766. Dividends amount to \$36,095. The balance is \$164. The technical committee, consisting of J. A. Agnew, J. H. Cordner-James, Theodore J. Hoover, and A. F. Kuehn, made the following remarks on some of the properties.

BURMA CORPORATION. The last official estimate of ore reserves at the beginning of July, 1916, gave 3,240,000 tons of ore already proved and probable above the Tiger tunnel, with anticipated extensions down to this opening of 650,000 tons. Owing to a concentration of effort on the completion of the adit, development has not proceeded as rapidly since the end of the last half-year as previously; nevertheless, such work as has been carried out justifies a further addition of 160,000 tons to the reserves, making a total of 3,400,000 tons. In addition to this tonnage, it may be safely estimated that there will be additions down to the Tiger tunnel of a further 600,000 tons. The total proved and probable ore and anticipated additions to the orebody above the tunnel is therefore, in round figures, 4,000,000 tons, averaging 25 oz. silver, 27 1/2% lead and 22 1/2% zinc. The Chinaman orebody has been developed for a length of 1200 ft., with a width varying up to 140 ft. The Tiger tunnel holed through to the internal shaft workings on September 24, thus confirming accurately the estimate made by the Technical Committee of the Burma Corporation. This tunnel has taken 29 months to drive 7300 ft., or a little over 250 ft. per month, which, considering the times, was excellent progress. The burden of pumping and hoisting will now be completely dispensed with, and development can proceed rapidly on the lower levels of the mine. That this is true is confirmed in the last published telegraphic report of the manager, which indicates that he is now in good grade ore on the Tiger tunnel level, assaying 29 oz. silver, 30% lead and 18% zinc. An interesting event will

now be in prospect, that is, extending of the Tiger tunnel through the orebody, thus opening the Chinaman orebody at a depth of some 700 ft. below the surface. This tunnel will also ultimately cut the vertical shaft workings and make available not only the high-grade lead-silver ore in that section, but also 30,000 tons of high-grade copper ore, assaying upwards of 15% copper. It is hoped to reach this position during the present high prices of copper. There are three furnaces in operation at the mine, and one of these can be readily converted to reduce copper ore.

Smelting operations have been carried on continuously, and the plant is now working at the rate of 3000 tons per month of ore from the mine and 500 tons of slag. From these the yield is a little over 1200 tons per month of lead and 70,000 oz. of silver, both of which products are realizing good prices.

Design of the new lead-concentrating mill is now practically completed, and detailed plans and specifications are being prepared for the first unit of 333 tons per day. Orders will shortly be placed for the machinery, and as manufacturers are able to promise fairly prompt delivery it is not anticipated that there will be much delay in installation. This unit will be followed shortly by two others of the same capacity, bringing the total up to 1000 tons per day. The Technical Committee has estimated the profit per ton at \$12 at pre-war prices of metals.

ZINC CORPORATION. Development continued throughout the year, the main shaft having reached a depth of 1522 ft. Exploration on No. 8 and 9 levels continues to show large bodies of good milling ore. On No. 10 the orebody has been proved as satisfactory by diamond-drilling and cross-cutting. Reserves show a considerable increase compared with the previous year.

Operations in the zinc treatment department were resumed at the beginning of the year. Unfortunately, owing to a strike, the plant was closed down from January 10 to February 14, this affecting adversely results of the first two months of 1916. However, up to the end of August, 28,863 tons of zinc concentrate was produced, which has been sold at remunerative prices. The lead mill has continued in operation at practically full capacity, with the exception of the first two months of the year, when the mine was closed down, and has produced 18,018 tons of lead concentrate. This output has been sent to the Broken Hill Associated Smelters, in terms of an agreement with that company, and at the high price of lead now prevailing shows a handsome profit. This company, at the prevailing price of metals, has therefore been earning profits at the rate of about \$96,000 per month, and during July and August, when the zinc plant was running full time, the profits were about \$145,000 per month.

LAKE VIEW AND STAR. During the six months to August 31 last this company treated 96,898 tons, which yielded bullion worth \$98,285, while the working expenses, including development, for the same period amounted to \$100,749. During the year ended February 28 last, dividends aggregating 15% on the company's capital were paid; no dividend has been distributed for the current year.

The estimate of ore in reserve on February 28 last was 353,527 tons worth \$6.20, compared with 426,301 tons worth \$6.40 at the close of the previous year. The figures do not include any ore in the Chaffers mine, in which, according to reports made before the mine closed down, are 74,892 tons worth \$7.30 per ton. The mine has been adversely affected by war conditions in combination with a run of low-grade ore in the stopes. The rise in the cost of supplies, shortage and inefficiency of labor, and inability to obtain bromo-cyanide, which had hitherto been considered essential for economic treatment of the ore, have in the aggregate added greatly to working costs, and increased the loss of gold in the residue. To meet the altered conditions a scheme of treatment without bromo-salts was evolved, and the plant adapted to the altered circumstances; but the new method of treat-

ment, although promising, does not so far give as good a commercial result as was obtained by the old system.

This property is at Kalgoorlie, Western Australia.

CENTRAL AMERICAN MINES. Since the date of the last report issued by this company great difficulties have arisen in connection with development in the bottom of the mine. The flooding of the No. 2 level and shaft, due to breaking into an accumulation of water in old Spanish workings in the San Basilio section, proved to be more serious than the first advices indicated; further difficulty arose later through the caving of the shaft timbers between the surface and No. 1 adit-level. The delays consequent on these happenings have, as may be realized, caused much delay in opening the third level. Further difficulties, directly attributable to the War, have arisen, and their accumulated effect is such as to make it impossible to continue working without some re-organization of the company's position. The cost of almost all stores has materially increased, wages have had to be raised to all classes of workmen, the exchange rates both in Nicaragua and America have disadvantageously operated, and shipping on the Pacific Coast is so infrequent and irregular as to derange repeatedly the company's operations. Under these circumstances the directors have under consideration the matter of suspending treatment operations, and continuing the development pending some immediate decision being arrived at regarding the re-financing of the company.

During the year ended December 31, 1915, there was 27,849 tons of ore treated for a yield of £47,194; working expenses amounted to £40,260, showing a profit on revenue account of £6934; of the latter, shaft-sinking absorbed £1020, mine development £1545, and construction and equipment £2024, leaving a net profit in the Republic of £2345.

BABILONIA GOLD MINES. The work carried out at this property has been, on the whole, of a satisfactory character. The east Crimea shoot has been opened on the second level, the west shoot on the same level has opened well, while of much importance is the finding of a practically continuous shoot of ore between these main blocks, in the hanging-wall portion of the orebody at No. 2 level, an area that hitherto had been regarded as valueless. The latter work led to further prospecting in the hanging wall of the No. 1 adit-level, and—more recently—in No. 2 adit, in each case with success. While this ore is lower in grade than the main east and west shoots on the Crimea vein, it is highly profitable.

The plant continues to give excellent results, both in the matter of capacity and extraction. For the year ended December 31, 1915, there was 9586 tons of ore and 5724 tons of accumulated slime treated for a return of £37,152. The expenditure under the heading of working costs was £24,445. The profit above working expenditure was £12,707, or a net profit of £5279, after allowing for the cost of mine development of £7428. This mine is in Nicaragua.

CONSOLIDATED INTERSTATE-CALLAHAN MINING CO.

In the third quarter of 1916, this company, operating in the Coeur d'Alene, Idaho, shipped 3297 tons of crude ore averaging 50.5% zinc, 14,184 tons of concentrate averaging 47.7% zinc, 388 tons of crude ore averaging 18.9% lead, and 1121 tons of concentrate averaging 19.4% lead. The total metal in the shipments was 16,868,836 lb. of zinc and 1,454,562 lb. of lead. The combined cost of mining and milling was \$6.302 per ton. The mill recovery was 85.7% of the metal-content, an increase of 4.71%. The net value of shipments was \$655,034, against \$997,182 for the preceding three months. The profit was \$413,695, compared with \$713,677. \$1.50 per share was distributed, totaling \$697,485.

The advance report on gold, silver, copper, and lead in South Dakota and Wyoming has been issued by the U. S. Geological Survey. The value of the precious metals was \$7,507,636 and \$15,018, respectively.

Industrial Notes

Information supplied by the manufacturers.

Improved Miner's Lamp

Two improved forms of the General Electric miner's lamp have been recently approved by the U. S. Bureau of Mines. Form C has a case of drawn and tinned sheet steel, while the form D battery container consists of 1-in. aluminum alloy casting, 99% pure aluminum. Otherwise the lamps are identical.

The cap lamp is a steel shell lined with fibre insulation, and contains the reflector of porcelain-enamelled steel and phosphor-bronze spring contacts rigidly mounted. The latter hold the Mazda lamp bulb in such manner that it is shattered and expelled from the contacts by a blow that otherwise

IMPROVED MINER'S LAMP.

would be only sufficient to crack or chip the glass bulb as usually mounted. This prevents the heated filament coming in contact with inflammable gas. Double steel hooks, electrically welded together and riveted to the shell, provide means for attaching the lamp to the miner's cap. The cap lamp is waterproof and weighs four ounces. The weight on the cap is from six to eight ounces, depending on how the lamp and cable are worn.

The lamp is a one-half candle power wire-drawn Mazda with a guaranteed life of 300 hours. It has two contact bases, and a single filament running straight through the bulb together with the reflector produce a well diffused illumination at an angle of 130°. A 13-in. cable connects the lamp to the battery. This is made for the unrestricted movement of the miner. It is double twisted strand copper, rubber coated individually and together and the whole rubber coated. The weight is 5 ounces. This construction gives a strong, light, flexible, non-linking cable, of low resistance. Protection at each end is afforded by steel spring armor, double at the battery and single at the lamp. The cable is fastened in the lamp and battery cover entrance by being held under pressure secured with lock-nut. It will stand a heavy strain without loosening or putting undue strain on the terminals of the conductor.

Both forms have approximate outside dimensions of thickness 2 in., height 6 1/2 in., and width 5 in. Total weight, form C, 4 lb. 7 oz. and form D, 4 lb. 13 oz. All metal parts are finished with a semitransparent gold proof lacquer, which gives a serviceable and pleasing appearance.

The battery is an non-leak exide, iron clad, self-contained and exide negative. It is guaranteed to give a capacity of at least 10 hours per charge for about a period of two years. The plates are contained in a medium weight rubber non-spillable case, ribbed vertically for strength and secured

with a special vent and filling plug. The cover is so constructed that the pressure of the contacts on the terminals strengthens the seal. All parts of the entire outfit are interchangeable. No gas is generated on discharge, and explosions are therefore impossible.

The outfit will operate submerged in water; it is safe, durable, efficient, and easy to wear; the light cannot be extinguished except by intentional disabling, and the outfit may be sealed so that tampering will be rendered visible.

Commercial Paragraphs

In Bulletin 64 the CHAIN BELT Co. of Milwaukee illustrates its chain-belt traveling water-screens, which are giving good results at large power-plants.

'Roebling Wire Rope' No. 4 contains notes on electric cranes, rope, tackle, slings, aerial conveyors, derrick, and increased efficiency in mine-rope service.

Denver 'Clipper' drills are the subject of Bulletin C-3 of the DENVER ROCK DRILL MANUFACTURING Co. Models 50 and 55 may be used as hand drills or mounted for any work about a mine or quarry.

Among the interesting mechanical notes in 'The Excavating Engineer' for October there is given the record of a class 45, 2 1/2-yard Atlantic (Bucyrus) steam-shovel that loaded 82,500 cu. yd. of sand and clay in 24 1/2 days of 10 hours each.

Manganese-steel sand and gravel-pumps, and wearing parts for pump-dredges are discussed in Bulletin 72 of the AMERICAN MANGANESE STEEL Co. of Chicago. The publication shows centrifugal-pump details, all parts of which are of manganese steel.

Railway motor gears and pinions are illustrated and discussed in Bulletin 14,419 of the GENERAL ELECTRIC Co. These wheels are of the forged or solid cast-steel make. Split wheels are reinforced and have lock-nuts on the bolts. Useful notes are given on correct and incorrect mesh of the teeth.

In the October issue of 'Leschen's Hercules,' St. Louis, some details are given of erecting a 60,000-kw. steam-power plant near Buffalo, how an aerial tram 584 ft. long across a river saved a two-mile haul in Wyoming; coal mining in West Virginia, and the beet-sugar industry of the United States. In all of these operations wire rope is used.

The NORDBERG Mfg. Co., of Milwaukee, Wis., announces the appointment of H. W. Dow as sales manager. He has been associated with the company in the engineering and sales departments for 12 years. The Nordberg company builds steam and electric hoists, Corliss engines, poppet-valve engines, millow engines, air-compressors, oil-engines, and Nordberg-Cards Diesel engines.

Single compressors, steam driven with balanced steam valve and automatic fly-wheel governor, are described in Bulletin 31-Z of the CHICAGO PORTLAND TOOL Co. Some details of construction are given, with a section showing the whole engine.

Bulletins 31-K and 31-X deal with fuel-oil driven compressors and engine gas engines. Considerably detailed photographs of parts are shown.

An unusually well-illustrated bulletin of the ALLIS-CHAMBERLAIN MANUFACTURING Co. of Milwaukee, Wisconsin, deals with pumping engines. The new type made is the horizontal, cross-compound, crank and fly-wheel pumping-engine, the latest step in the evolution of high-duty pumping-engines. Considerable detail, with drawings, is given on this machine; also indicator cards of tests. In Bulletin No. 1810 this firm illustrates a ball-steel jaw-crusher, made in three sizes, namely, 36 by 24 by 18, 36 and 60 by 18. A picture shows a double-drum automatic electric hoist for rock-crushing plants.

EDITORIAL

T. A. RICKARD, Editor

COPPER at 33 cents has reached the highest price since 1873. A 'famine' is claimed to exist at New York. Urgent demand is reported for April and May delivery. Most of the producers are out of the market until July of next year. Spot copper has disappeared as an item of trade.

STRONTIUM NITRATE is a chemical product that is now being made in California, as described on another page by Mr. Donald F. Irvin. The mineral celestite, the sulphate of strontium, is one of the ores found in the southern part of this State, and the manufacture of the nitrate is done locally at Los Angeles and Long Beach.

UPON another page we give some notes on the hearing of the Hyde flotation case before the Supreme Court. Nearly three days were given to the arguments and it is said that a more distinguished group of counsel has rarely thronged the Capitol. The decision may be delayed by the technical intricacy of the subject, but it is expected before the close of the year.

OUR French contemporary *L'Echo des Mines* acknowledges the efficiency exhibited by the Austrians in re-opening the Serbian mines after the tide of military invasion had passed. Copper, lead, and antimony are being produced in considerable tonnage at various points, such as Rudnik, Cavonj Breg, Dorspotok, and Majdanpek. The work is being done under military organization.

MISGIVINGS over our phenomenal prosperity are multiplying; and it is a good sign. Something is needed to curb the debauch of speculation that is now in full swing. The sagacious captain of industry will deprecate the assumption that present conditions can persist and he will prepare for the shock of peace that will come as surely as the crisis that followed the declaration of war nearly 2½ years ago.

THANKSGIVING finds the people of the United States enjoying a peaceful prosperity that is all the more remarkable by force of contrast with the conditions obtaining in Europe. The President's proclamation of November 30 "as a day of national thanksgiving and prayer" not only urges our people "to resort to their places of worship . . . to render thanks" but it also suggests that they should "think in deep sympathy of the stricken peoples . . . upon whom the curse and terror of war have so pitilessly fallen," and it recommends

them to contribute of their abundant means to the relief of suffering. That was a worthy touch and we hope it may be heeded.

PLAGIARISM of the unconscious kind is not deemed a terrible sin, but deliberate plagiarism finds little excuse. Recently we drew attention to the use of the title 'The Flotation Process' by a New York publisher after that title had been used for a book published by us. Now a mining paper at Chicago follows the example of the New York publisher and issues a third book on the same subject under the same name. The title of a book cannot be copyrighted by law, but there is a convention of good taste that usually suffices to prevent confusing, if not misleading, employment of any name already in use. Some people have a lot of taste, but it is all bad. We think it proper to draw the attention of the profession to a trespass that is both stupid and indecent, and we express surprise that the respective authors, Messrs. Herbert A. Megraw and H. J. Stander, should have lent themselves to such a performance. That redoubtable Arizonan hero, Billy the Kid, would call it "plumb mean."

IT is six years since the beginning of the Madero revolution and yet Mexico is no nearer the political reform of which he dreamed. The Joint Commission, having served to postpone fresh complications until after our presidential election, is about to be dismissed, without result. Arrangements for patrolling the border are of small consequence compared with the ending of the bloody anarchy to which the country is still subject or the taking of some measures to protect the lives and property of our citizens operating there under the implied sanction both of their own Government and that of Mexico. The Carranza government is now insisting upon a return to the 1912 scale of wages at the mines and upon payment in gold, at a time when exchange stands at 60:1. Letters from Mexico bear a stamp of one peso, instead of the 5-centavo stamp that formerly sufficed for postage. Conditions at the mines are precarious and strikes have been started in several localities, notably in Jalisco.

FLOTATION in its simplest and most effective application is illustrated in the article by Mr. Hallet R. Robbins describing the Union mill of the Calaveras Copper Company. The simplicity of the flow-sheet will appeal to mill-men; so will Mr. Robbins' admirably clear description. Chalcopyrite in schist makes an ore readily amenable to flotation, as we have seen at the Britannia. The excess of barren pyrite might have proved an ob-

stacle to concentration by froth, as it was to ordinary wet gravity methods, but fortunately the greater hardness of the pyrite (6 to 6½) as compared with the chalcopyrite (3 to 3½) causes the former to break more coarsely and so deters the flotation of it in favor of the copper-bearing sulphide. Here we have an example of selective crushing followed by preferential flotation. In some respects the Calaveras treatment resembles that at Engels, as described in our issue of July 31, 1915. At Engels, magnetite proved a deterrent to water concentration, diluting the percentage of copper in the concentrate, and there also the difference between the hardness of the chalcopyrite and its associated sulphides became an aid to flotation. This process requires fine grinding, which is in most cases a favorable economic factor because the closer comminution of sulphides is inevitably accessory to the crushing of them. On the other hand, the need for fine grinding precedent to flotation may prevent the adoption of the froth process as against cyanidation, particularly in mills treating ores valuable chiefly for their gold contents. The success of the work at the Union mill is imputed by Mr. Robbins to the adoption of the pneumatic method of making froth; he gives a detailed drawing showing in what way the porous bottom differs from the conventional type and he describes the manipulation of the 'air-pans.' It will be noted that the consumption of oil is low—less than ½ pound per ton of ore. The best tribute to the excellence of the metallurgical treatment is the poverty of the tailing, which contains as little as 0.01% copper. Truly it is a result that does credit to all concerned. The recovery is over 96%, this splendid figure comparing with the 50% recovered by ordinary water concentration. This is another remarkable tribute to the efficiency of the flotation process.

TAXATION of mines is threatening to injure business in the city of London. For many years the British metropolis was the mining centre of the world but it is becoming recognized that the heavy taxation incidental to the War may make it undesirable to register mining companies at Somerset House or to direct them from the north bank of the Thames. An equally important factor is the probable discouragement to the British public, which during the last half-century has been the most consistent and courageous supporter of mining enterprise. Unfortunately the economies of mining are not understood by the tax collector, chiefly because he has been misled by his victims into believing that a mine is an 'investment' and that dividends are 'income.' An engineer described as 'a mining authority of world wide reputation,' writing in Mr. F. W. Hirst's new paper, *Common Sense*, says: "A mine with ten years to run, which is only paying 10%, is paying no interest at all to the man who buys its shares at par." The sense is as good as the writing is done by. "A mine is a wasting asset and until the capital spent in purchasing, equipping and developing it has been redeemed no part of the earnings is a true profit. Flimboy int financiers long ago started to give the name of 'dividend' to a finan-

cial return of capital because by doing so they suggested a highly profitable kind of business. The tax-collector took them at their word and the industry of mining became burdened with an unfair impost. Now the income-tax of 4s. on the pound, or 20%, appears an intolerable hardship to the shareholders. Indeed it is—particularly to such as reside not in Great Britain but in a non-belligerent country. The foreign shareholders constitute an important element in the mining business of London; most of them appreciate the convenience of a headquarters in London and the efficient clerical service obtainable there. These head offices are a source of great profit to the City, both in rent and in salaries. It will be a serious matter to a number of worthy people if mining companies cease to be incubated and nursed in London. The 5% income-tax was no great burden before the War, but when it is quadrupled, with chances of further increase, the exaction becomes prohibitive. The result will be a transfer of registry wholesale unless the British authorities awaken to the position. Capital is a sensitive plant.

SPECTULATION in stocks of mining prospects is the subject of a letter appearing on another page. We are glad to give space to it, for not only is Mr. Ira B. Joralemon a mining geologist well known to us by reputation, but we appreciate the public spirit that was the motive of his warning. He states the case tersely: "A 100:1 shot is sometimes a good gamble; but a 100:1 shot for a 20:1 profit is obviously poor business." Undoubtedly the spectacular discovery in the United Verde Extension and the crop of millionaires that it sowed in Arizona has had a pernicious influence, for while the story of such a mining adventure is one to warm the cockles of the heart, the use of the incident as a sample of experience is grossly misleading. We accept Mr. Joralemon's correction of a reported discovery of rich ore. That item of news appeared in an article written by the Director of the Arizona Bureau of Mines; which only goes to show how difficult it is to obtain accurate information. On the other hand, the gossip of the plaza is interesting to many, even as unconfirmed gossip; what is needed in these matters is the drawing of a distinct line between what is gossip and what is personal knowledge. Both are interesting, but they are not to be taken in the same way. The exigencies of time prevent an editor from communicating by letter with the managements of mining companies, to confirm or correct information concerning developments underground. We regret to say that the managers are rarely permitted to give such information, and there is where the mischief begins. If the mining companies authorized their managers and superintendents to issue correct information concerning the finding or the losing—of ore in the mines, there would be less opportunity, not for speculation, but for deception. We are always grateful to any of our readers that transmit news of current mining developments and we hope that a personal invitation to do so may not be deemed necessary.

A Matter of Principle

Discussion of the Shockley episode is re-opened by a letter that we publish from Mr. Edward W. Parker, one of the members of the Anthracite Section of the Institute that took it upon themselves to censor his paper in the transactions of the Engineering Congress, as related in our issue of October 21. We welcome Mr. Parker's rejoinder as furnishing a further opportunity to make clear the facts of the case. He suggests that it is "an unpleasant incident which it were better to have left buried." We disagree; when a wrong is done to a member of our profession, it is best to defend him and to see that justice is done, in the hope of preventing a repetition. As regards the San Francisco Section, it is well to state that the committee appointed to draft the resolution on the subject consisted of Messrs. D. M. Riordan, Frank H. Probert, and F. H. Harvey. None of these needs any introduction. Mr. Harvey was chosen particularly because he has practised as an engineer in the anthracite region and is familiar with the conditions upon which Mr. Shockley had animadverted. Mr. Parker is in error in stating that Mr. Shockley refused to correct any statements in his paper; on the contrary, he agreed promptly to correct any statements that were shown to be wrong, and in his revised paper—before the censoring—he did make sundry corrections, omitting controversial matter that did not have the support of Government reports. No proof of misquotation by Mr. Shockley has been furnished by Mr. Parker or his associates in the employ of the anthracite companies. It is possible that errors did exist in a paper so full of figures, and we do not doubt Mr. Shockley's entire willingness to correct any such errors, if they had existed and if they had been pointed out. Whether the report of the Immigration Commission is correct or not, it is an official report and can be discredited only by definite statistics. Whether Nearing's book is a good or a bad one is beside the mark, since the only use of the book made by Mr. Shockley was to quote from it the statistics issued by the Secretary of Internal Affairs for the State of Pennsylvania. Whether Nearing is a socialistic villain, or not, does not arise in this controversy; the figures to which objection was made were those of an official of the State of Pennsylvania. We might as well refuse to consider Mr. Parker's figures because he is in the employ of the anthracite trust. He writes to us as the manager of the Anthracite Bureau of Information. Yes, the editor has had some experience of statistics, although not as much as Mr. Parker; he has had enough to know that of all kinds of information the statistical is the easiest twisted to suit the purpose of an argument; he knows enough to be aware that the statistics compiled for the employers in a labor controversy are just as unreliable as those prepared by the unions. For the failure to omit the statement on pages 42 and 43, the Anthracite Section is responsible; they did not ask to have it omitted and Mr. Shockley informs us that he had forgotten it was in the paper until Mr. Hohl called attention to it in our issue of October 21. Mr. Shockley did

omit all the statements to which objection was taken by the Anthracite group in their letters to the chairman of the Engineering Congress. Mr. Parker's confident assertion, now made, that "the anthracite miners are paid as high wages as the workmen in any employment requiring equal skill and application, and they are better paid than many" is probably incorrect. The Colorado operators state, on page 45 of their pamphlet: "Colorado coal miners are, and have been for many years, earning better wages than miners in any other part of the United States," and on page 5 of the same pamphlet are the figures quoted by Mr. Parker from Mr. Shockley's paper, showing that the average earnings at the two groups of Colorado mines mentioned were \$1100.75 and \$999.36. Mr. Shockley took the average of these as \$1050; and as his figure for the average earnings of the anthracite miner was \$503, it is plain how he arrived at his conclusion. Mr. Parker's estimate of the earnings of the anthracite miner is \$628, on which basis the Colorado miner earns two-thirds more. We leave it to Mr. Parker to reconcile these figures with his over-confident assertion regarding an equality of wages.

But this dispute over statistics is a herring across the trail. The San Francisco Section passed no judgment whatever upon conditions in the anthracite region—to do that it was not competent. It went on record as saying that the action of the directors of the Institute in censoring Mr. Shockley's paper was unwarrantable, and as yet we have seen no reason for questioning the justice of that decision. If the San Francisco section had been called upon to express an opinion on the action of the Anthracite Section, it is more than likely that it would have condemned the impertinent telegram sent to the Engineering Congress and the top-lofty attitude assumed by the gentlemen at Wilkes-Barre. Our own careful inquiry into the facts justifies the statement that Mr. Shockley has shown much greater sense of courtesy than his opponents and that his final agreement to withdraw the offending paragraph—which he need not have done—was marked by a consideration for the Chairman of the Engineering Congress that that gentleman should acknowledge gratefully. Mr. Parker's charge of animus and carelessness is not sustained by the evidence of the paper. A jury of his peers in San Francisco has absolved Mr. Shockley from any such indictment by the representative of the anthracite coal companies. We find an explanation of the whole controversy in the hysterical hyper-sensitiveness of the anthracite operators. We recall how the late Joseph A. Holmes, as director of the U. S. Bureau of Mines, was subjected to violent abuse because he dared, in one of his reports, to criticize the wasteful methods in vogue at the anthracite mines. The constant attitude of the operators is a watchful waiting to resent criticism. Mr. Parker, as their agent of publicity, questions the propriety of criticizing the conditions of an industry with which the critic is not familiar. Mr. Shockley has been in the anthracite region and so have others on this side of the Sierra Nevada. One does not need to live at Wilkes-Barre to understand the merits of a controversy, the chief point of which is not the rela-

tive accuracy of statistical data, but the propriety of one section of the Institute censoring a paper written by a member of another section, not in the transactions of our Institute, but in the records of a Congress by which the supposedly offending paper had been invited, accepted, edited, printed, and circulated.

British Columbia

Just north of the international line—a line on which neither fort nor soldier stands on guard—there is a mineral region of great interest and beauty. The big river that bears a name expressing the poetic impersonation of the United States has given its name also to a Canadian province that ought to be better known to the mining engineer, for it is as rich and varied in its resources as it is picturesque and healthful in its physiography. British Columbia has an area of 382,000 square miles, of which 250,000 square miles is mineralized. Since the population is only 400,000, it can be understood that much of this mountainous country has not been explored or 'prospected' with any sort of finality. That so large an undeveloped, and also habitable, area should exist on this continent is due to the geographic position of the region and the lack, until recently, of the railways so essential to organized industry. During the last five years an impetus to exploitation has been given by the building of two or three new railways, which, although designed primarily to convey the grain of the plains east of the Rocky Mountains to the western seaboard of Canada, have also afforded the facilities required for mining on a large scale. In consequence, the mining industry has undergone notable expansion. In 1915 the mineral output of the province was worth \$29,500,000, and for the first time the copper production exceeded in value that of the coal. The metallic production was the largest in the history of the Province, making a total of \$20,762,000, distributed as follows:

Gold	\$5,937,934
Silver	1,588,591
Lead	1,939,200
Copper	9,835,500
Zinc	1,460,521

The most notable advance was made in the yield of copper, which increased 26.46%. At the present time British Columbia can boast two copper mines of the first magnitude, the Hidden Creek, at Anyox, on Observatory Inlet, and the Britannia, on Howe Sound. The first of these is owned by the Granby Consolidated Mining, Smelting & Power Company, which has been working the Phoenix mines, in the Boundary district, since 1901, and is now compensating for the approaching exhaustion of its old property by developing new and larger resources in the mine on the coast, acquired in 1912. The total ore reserves now available there are estimated at about 10,000,000 tons averaging 2½% copper and about 1,000,000 tons averaging 1½% copper. The Britannia, owned by the Britannia Mining & Smelting Co., has even larger potentialities, for it owns an enormous tract of

copper-bearing schist in which it is estimated that about 17,000,000 tons of 2% ore is reasonably assured. Generalizing, it may be said that the main interest in copper mining has shifted from the interior of the Province to the coast, creating enterprises of a peculiarly attractive kind, owing to easy accessibility. Undoubtedly further search will lead to the uncovering of more low-grade but expansive undertakings in the mining belt adjoining salt water. From Britannia to Anyox the distance is 550 miles and all of it is well worthy of careful prospecting.

The lead and silver productions of the Province are derived mainly from the Slocan and Fort Steele districts. In the latter is the Sullivan mine, containing one of the big orebodies of the world, but so refractory, owing to its zinc content, that until recently it had but scant commercial value. This has been remedied by the successful introduction of the electrolytic zinc process at the Trail smelter, which, like the Sullivan mine, is owned by the Consolidated Mining & Smelting Company of Canada. The old silver-lead mines of the Slocan, especially at Ainsworth, Sandon, and Silverton, are undergoing a revival, owing to the stimulation of higher metal prices. The War, of course, has given an impetus to mining all over the Province, because the intensive demand for metals has created a good market. On the other hand, the splendidly patriotic response of the people of British Columbia has depleted the mining population and caused a scarcity of labor, corrected in part by immigration from the United States and Japan. As regards gold mining, the yield of the placer mines is relatively small, only \$770,000, but it improved in 1915, thanks to a fairly good season in the Atlin and Cariboo districts. On the other hand, the lode mines in the Boundary and Rossland districts did better and several new finds, notably the Surf Inlet, were recorded in the Coast district; but a large part of the gold comes as a by-product in the smelting of base-metal ores, particularly those of copper. As yet no extension of the Juneau belt has been traced from Alaska southward into British Columbia, but it will be strange if intelligent exploration along the Coast range does not uncover similar lode-channels containing low-grade but extensive orebodies. The coast is indented so as to furnish easy access by water to this promising belt of mineral country and we expect therefore that under the existing stimulus to the search for metals there will ensue many new discoveries, both of gold and copper. The Provincial Government is friendly to foreign capital, using that word in its technical sense and meaning American money. At the present time most of the successful mining being done in British Columbia is financed from this side of the line. For reasons into which we shall enquire on another occasion, it is a fact that British capital is now no longer conspicuous in British Columbia, the big things, with the exception of the Trail smelter and its associated mines, being controlled by Americans. Nowhere is the American given a heartier welcome. To the capitalist and to the engineer from this country British Columbia offers a fine field of enterprise; we commend it to their attention.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

A Matter of Principle

The Editor:

Sir—Two articles contained in your issue of October 21—one an editorial, the other a letter of discussion—both entitled 'A Matter of Principle,' and the protest by Mr. Shockley at the action of the board of directors of the American Institute of Mining Engineers, revive an unpleasant incident which it were better to have left buried. This is also true of the act of the San Francisco Section of the Institute, which passed a resolution apparently entirely on *ex parte* evidence and on a matter with which it was not in any way familiar.

At the time that Mr. Shockley's paper was presented before the International Engineering Congress both Mr. Norris and Mr. Ludlow, who were the only anthracite men present, protested against certain statements contained therein and desired to have them corrected. Mr. Shockley, however, treated the protests of these gentlemen with scant courtesy, refused to have any correction made of the statements contained in his paper, and evinced a decided resentment of any criticism of such statements. As they could not get him to correct his statements, their only recourse was to protest as they did to the board of directors of the Institute through the Anthracite Section.

Some of the statements made in Mr. Shockley's paper did great injustice to the operators in the anthracite region, but even that might be excused if many of the figures used had not been misquoted or misapplied. The fact of the matter is that the paper not only showed animus, but a carelessness in the use of figures to which a stronger term might be applied. I know this because it devolved upon me to try to verify some of Mr. Shockley's statements.

The report of the Immigration Commission, of which he made much use and from which he erroneously quoted, was not only more than a decade old, but was not compiled from any reliable official data. If the editor of the MINING AND SCIENTIFIC PRESS had had as much experience with statistical work as the writer has had, he would know that any Congressional Commission usually compiles statistics to suit its purposes. The MINING AND SCIENTIFIC PRESS may take my assurance of the fact that the report of the Immigration Commission was not made up of any reliable data collected from the anthracite region.

It is hardly worth while to comment on the use by Mr. Shockley of information (?) contained in Nearing's book on 'Anthracite.' Nearing was practically engaged

by the United Mine Workers of America to prepare this book in advance of the wage conference last April, and it was supposed that this publication would have great weight in fixing public opinion favorable to the cause of the United Mine Workers. It is somewhat trite to say that any act or thing has acted as a boomerang, but that was certainly the case in this instance. Nearing's book was so palpably inaccurate and irresponsible, was shot so full of holes by the reviews made of it, that I am informed it was never referred to in the wage conference. It was practically disowned by its own father. Nearing himself is now recognized as a radical of the most pronounced type and his statements should not be taken seriously by thinking people. By his own acts and utterances he has completely vindicated the action of the Board of Trustees of the University of Pennsylvania in separating him from that institution.

Both of these men, Mr. Shockley and Dr. Nearing, have presumed to write about the conditions in the anthracite region, neither of them ever having been in the region and neither having been informed as to the reliability of the information upon which they have attempted to draw conclusions and to influence public opinion.

In spite of all that has been done, however, by the anthracite section to prevent any misleading statements of this region and this industry in the Proceedings of the Congress, I note that Mr. Shockley has been able to get in one statement, which is quoted in Mr. Hohl's letter, and which is, you may take it from me, not in accordance with fact. This statement occurs on pages 42 and 43 of the report of the Congress and is as follows:

"According to the mine operators' statement, these miners (Southern Colorado) are making the highest wages of any coal miners in the United States: the annual wages for all miners in the Victor American Fuel Co. for the year ending June 30, 1913, were \$1100.75; for the same period the miners of the Colorado Fuel & Iron Co. made \$999.36; the average being more than twice that of the anthracite miners of Pennsylvania." (Italics mine).

It would be interesting to know Mr. Shockley's authority for this statement. The anthracite miners are paid as high wages as the workmen in any employment requiring equal skill and application, and they are far better paid than many.

Aside from all this, however, it seems to the writer that the action of the San Francisco Section and of the MINING AND SCIENTIFIC PRESS in attempting to pass

judgment upon a matter affecting a region and an industry with which they are not at all familiar, is not in conformity with the ethics of the mining engineering profession. If the gold-mining or petroleum-producing industries of California had been made the subject of gross injustice in a paper before such a dignified organization as the International Engineering Congress by a member from the Atlantic Coast who was not familiar with the conditions, and if the San Francisco Section had taken steps to see that the matter was corrected before its publication to the world, or, if not corrected, suppressed, it is not believed that the anthracite, the New York, or any other eastern section, would have entered objection thereto.

E. W. PARKER.

Wilkes-Barre, Pa., November 6.

Gambling in Shares

The Editor:

Sir: During a mining boom like the one we are now enjoying in Arizona, it seems to me that the technical journals have an important duty which is being overlooked. This is to try to curb excessive speculation in stocks of mining prospects, or at least to try to see that the gambling is done at odds which give the public a fair chance. A hundred to one shot is sometimes a good gamble. But a hundred to one shot for a twenty to one profit is obviously poor business. This is the sort of gambling which is now being done by those who buy stock in nearly any of the new development companies in the South west.

During the past year dozens of companies have been formed or resuscitated to develop prospects in the Jerome district and other parts of Arizona. Usually the point most emphasized in advertising these companies is the fact that they are within a mile or two of great producing mines. With possibly one or two exceptions, the very best that can be said of the prospects is that they are worth developing. Hardly one of them has a ton of ore developed, and many others expose only recent rocks which have no bearing whatsoever on any possible mineralization in the older underlying formations. It is surely reckless to value such prospects at figures much greater than the sum which must be spent in developing them. This should in no case greatly exceed half or three-quarters of a million dollars. But these new companies, instead of having a stock valuation of half a million dollars, are now selling at figures which give them a value of from two to ten or fifteen millions. These prospects, certainly, do not stand more than one chance in ten of making mines. Assuming that one in ten will make a mine worth from ten to fifty million dollars, those who buy stocks at the present prices are taking a one in ten chance for a profit of from two to five for one. This is certainly poor gambling.

It is true that, at the issue prices, many of the new companies did not have a capitalization greatly in excess of the money needed to develop them. It is the speculation since the issuing of the stock which has caused the

inflation and which will cause hundreds of people, many of whom cannot afford to throw away money, to lose tens of millions of dollars within the next two or three years. The result will surely be a great injury to the good name of Arizona and of the mining profession.

It seems to me that the technical journals can help a great deal by trying to educate the public to distinguish between a legitimate mining gamble and a gamble at outrageous odds. This may be a hopeless task when the sight of the easily won fortunes in Verde Extension and other stocks have turned the heads of so many people. If they cannot help in this way, the journals should certainly be most careful not to print untrue or exaggerated stories of the discovery of ore by these new companies. Such stories often come in articles which should be authoritative. For instance in your issue of November 1, in the article on 'Mining in the Jerome District' there is a report of a discovery of a rich ore-body in a property the management of which does not claim to have any ore whatever. The gossip of the 'plaza miners' should not find a place in a journal with a standard as high as that you set.

The managements of nearly all of these new companies are honest, though sometimes lacking in experience. Most of them are trying to find ore and not to swindle a gullible public. I wish to suggest therefore that before publishing reports of the discovery of ore by those development companies you communicate with the managers and have the statements verified. I feel sure that this precaution will prevent many people from buying stock at exorbitant prices, and will greatly help the mining industry.

IRA B. JORALEMON.

Warren, Arizona, November 8.

THE OCCURRENCE of tungsten ores, particularly scheelite, in contact-metamorphic rocks in which garnet is a prominent constituent is known in numerous places in California, Nevada, and elsewhere and is thought by many to be something quite out of the ordinary. Such, however, is not the case, for a tungsten mine of this description was successfully operated as long ago, at least, as 1898 in Connecticut. The deposit occurred at contact of limestone and schist in a zone of contact metamorphism. The minerals were chiefly garnet, epidote, hornblende and quartz. The ore averaged about 5% tungstic oxide and was accompanied by a small amount of pyrite. The milling of this material was entirely unlike anything thus far attempted in the West. The rock was crushed in breakers, passed through rolls, and then concentrated on what were known as pneumatic separators, a sort of dry concentration device. The recovery was stated to have been satisfactory and the product up to 65% tungstic acid.

THE deepest drill hole in the world is said to be one in upper Silesia where a prospect bore-hole was cut by a diamond drill to a depth of 7317 ft. This hole is 1.44 ft. in diameter at the surface, diminishing with depth to 0.157 ft. at the bottom.

VIEW FROM THE OUTCROP OF THE VEIN.

The Blue Bell Mine, Riondel, B. C.

By T. A. Rickard

While visiting the Kootenay region recently, I was a guest of Mr. Samuel S. Fowler at Riondel, and from him* obtained a number of notes on the romantic story of the Blue Bell mine, now owned by the New Canadian Metal Co., a French organization, for which Mr. Fowler is resident manager.

This lead deposit is said to have been the first exploited in the Kootenay region, the outcrop being visible from the lake, so as to attract the attention of the Indians and Hudson's Bay trappers, who worked the ore to obtain lead for the making of the bullets used in their muzzle-loading rifles. The year 1825 is given as the earliest date of such rudimentary mining and metallurgy in this locality. A veteran employee of the Hudson's Bay Company has testified that the trappers used to talk of the lead they obtained here and complained that it was so hard as to scour their gun-barrels. The presence of arsenic in the lead may have been the cause. The botanist Douglas is said to have visited the mine in 1825. In 1883 the principal claims were located.

The mine is situated on a peninsula projecting into the east side of Lake Kootenay. From the water it looks like a wooded island close to the shore. The highest point is 250 ft. above the water.

To understand the story of the Blue Bell, it is necessary to recall the early exploration of this mineral region. In 1865 gold was found in the upper watershed

of the Columbia river. The scene of these early discoveries was on French, McCulloch, and Carnes creeks, which are tributary to the Big Bend of the Columbia, namely, that part of its course north of Revelstoke, about Lat. 52° 10' N., where it ceases to flow north and makes a big curve before starting southward to the sea at Astoria, in Oregon. During 1866 there was a rush to the localities just mentioned and a good deal of gold was won. Transport by row-boats was expensive, so the Oregon Steam Navigation Company sent a Capt. White to Colville (Washington) to superintend the building of a stern-wheel steamer. This was in the fall of '67. In the following June this boat, called the *Forty-Niner*, made her first attempt to pass through the canyon above Revelstoke, failing at first but succeeding when the water had fallen. For several years White ran this boat successfully between Little Dalles (Washington) and the Big Bend country. On his last trip, however, being ill himself and anxious to obtain medical help, he tried to run the steamer down the rapids of the Dalles de Mort canyon (locally known as Death Rapids) above Revelstoke, at a time when the water was low. The steamer struck a rock and had to be beached, the crew going to Colville in a row-boat. The *Forty-Niner* was raised by Capt. A. Pingston, who ran her while any business was offered, but that was not long, because the Big Bend placer mines petered out in two or three years or proved unworkable because of boulders. She was laid-up above the Little Dalles canyon, 25 miles from Colville, or

*He, in turn, having obtained much of his information from A. D. Wheeler, of Ainsworth.

Marcus as it is now known. Later, Capt. Pingston himself died there suddenly in consequence of an accident, but he played a part in the Blue Bell story before he went over the range. It was after the steamer stopped running that Pingston made a trip, in 1871, with George Hearst, of California, to the Kootenay. It is related that in 1867 some prospectors had built a small furnace near the deposit of lead ore and that a sample of the bullion served to interest Hearst, afterward a famous mine operator and United States Senator, of whom it may be said further that his estate, through Mrs. Hearst, furnished the money for the erection of the handsome building in which is housed the Mining Department of the University of California. Another version of the story is that Hearst was shown a sample, not of bullion, but of high-grade silver lead ore, which the prospector, Henry Doan, had obtained in Colorado. The Blue Bell ore contains only $\frac{1}{2}$ oz. of silver per unit of lead. At that time Hearst was not yet a capitalist, but was acting as expert for others. He came from San Francisco with Capt. Pingston by way of Colville and the Columbia river. With him he brought an assay outfit and an assayer named Meyers, as well as the prospector who had induced Hearst to organize the expedition. This man, Doan, suggested to Pingston that the assay outfit might be lost while making a portage, but the captain ignored the sinister suggestion. On arrival at the mine, Hearst soon ascertained that he had been brought on a wild-goose chase. He could find no ore resembling the sample shown to him at San Francisco by Doan. Disgusted, he prepared to return, refusing to take Doan on his boat; he would have marooned him if Pingston had not intervened. These facts were related by Pingston himself to Mr. William Fernie, who at that time was Government agent in the Kootenay district. Another version of the story is that Doan tried to get the Indians in the party to throw the assay outfit overboard, telling them it was hoodoo. Doan acknowledged this deception after samples from the mine had been assayed on the spot. He was compelled to surrender what was left of the \$1000 paid to him on a \$10,000 bond, so that he got away with very little money. These items of information are furnished by Mr. Ben Burgunder of Colfax, Washington.

Now we come to another chapter in the story. In 1878 R. E. Sproule located all the available ground on the peninsula which covers about 140 acres. The principal claim was called the Blue Bell. Sproule, however, was not the discoverer nor was he the first locator on the hole, which had been recorded and abandoned several times before he came into the story. At that date the law required that the locator declare on oath in court that he was working on his claim. The impossibility of one man representing more than three claims was obvious. Whereupon Thomas Hammill, in 1882, filed counter claims on some of Sproule's locations. At that time Hammill was scouting for John C. Ainsworth, of Boise. George J. Ainsworth, both of Portland, Ore., were the owners of steamboat capitalists and also owners of the *Ainsworth*, the second steamer to ply between Revelstoke and the Arco

lean boundary line. The Ainsworths had secured a franchise for a railroad between the Columbia river and Lake Kootenay, the line that now runs from Robson to Nelson. To gain information previous to selecting land under the terms of their grant they sent Hammill on an exploring trip, accompanied by two other men.

In due course the conflict between Sproule and Hammill came before the magistrate at Fort Steele. The decision went against Sproule, but he was permitted to select three claims. He chose the Blue Bell, the Goldconda, and Silver King. Hammill took the Comfort and Kootenay Chief. The costs of the action, about \$3000, were taxed against Sproule and when he failed to pay the sheriff, the latter offered one-third of the Blue Bell at public sale. This interest was bought by Hammill on behalf of the Ainsworths.

Under the old law the locator was required to re-record his claim yearly, on pain of forfeiture. In the spring of '85 Sproule recorded the Blue Bell in his own name, ignoring the Ainsworth interest in the claim. Thereupon Hammill likewise recorded the whole claim in the name of the Ainsworths, ignoring Sproule's interest. On the day following Hammill's recording, Sproule threatened to kill Hammill if he set foot on the claim; the next day Hammill was found mortally wounded on the claim. He had been shot, and he died a few minutes after being found. Sproule had escaped in a boat an hour before the discovery of the crime; he was chased by the constable in another boat, and, being about to be overtaken, he landed, ascending the mountain a few miles south of Procter, which is 12 miles south-west of Riondel. Sproule was intercepted near the international boundary and underwent preliminary trial at Galena Bay, at the south end of the Blue Bell peninsula. He was found guilty and hanged at New Westminster. The Ainsworths pensioned Hammill's mother.

In the late autumn of 1884 Dr. Wilbur A. Hendryx had visited the mine and entered into an agreement with Sproule whereby Hendryx, his brother, and some parties in Minnesota and Connecticut became co-owners in the Blue Bell. When Sproule was executed they became sole owners, for the Ainsworths had forfeited their interest through the neglect of their attorney to redeem the \$3000 tax claim levied by the sheriff. Hendryx placed a steam launch, the *Surprise*, on the lake and river; he also started the work of sinking an incline on the Blue Bell lode. A portion of that incline is still to be seen near the top of the glory hole. In the year following—1885—he drove an adit from the east side and cut into a large orebody, subsequently mined as the 'vaulted chamber'. This showing prompted the driving, in 1892, of the lower adit from the lake-shore, under the direction of John R. Parks, Columbia '80, who was consulting engineer to Hendryx. Hendryx had good financial backing and became prominent in Kootenay mining affairs. He established the town of Pilot Bay and built a small coal smelter there in 1894. But the conditions were unaccusable and the plant was shut-down in 1895. Financial trouble beset him and the Blue Bell

property passed into the hands of the Bank of Montreal, which, in the summer of 1905, sold it to the Canadian Metal Co., a French organization headed by Edouard Riondel, who built a zinc-retort smelter at Frank (Alberta), discarding the use of the Pilot Bay concentrating plant and lead smelter. The zinc enterprise failed, running the company into debt, so that it was on the verge of complete collapse. In the summer of 1896 Mr. Fowler reported on the whole undertaking and became manager immediately thereafter. The present concentrating mill at Riondel, close to the mine, was built in 1907. It treats 250 tons per day and is of the conventional type: Blake crushers, rolls, jigs, trommels, Wilfley and Deister tables. The re-grinding is done in Huntington mills. These operations yield a concentrate in the ratio of 10:1, containing 48% lead, 12 oz. silver per ton, and 3% zinc, which is shipped to the smelter at Trail. The freightage is \$1.35, plus 20c. per ton for transfer from the barges.

in which the concentrate is loaded, into the railway-cars, at Procter in winter, if the arm of the lake happens to be frozen, and at Nelson in summer. The smelting-rate is satisfactory. The company is operating at a profit, increased recently by the favorable metal market. The mine is now 600 ft. deep on an incline of 35°. The deposit is a replacement in limestone, the irregular masses of ore following the bedding, with tongues projecting into the foot-wall country. This consists of pre-Cambrian sediments (underlying the Beltian series of the Coeur d'Alene) into which intrude granitic dikes, probably connecting with the Nelson batholith of granite, which is of post-Jurassic age.

Thus the story ends on a dry technical note; but the earlier paragraphs will have served to prove that the biographies of mines, as of man, are profitable reading, in so far as they convey a lesson and a warning to those that follow.

Zinc Production at Butte

The third report of the Butte & Superior Mining Co. for the current year gives the following data:

	Third quarter	Second quarter
Ore milled, tons.....	136,130	161,270
Zinc-content, per cent.....	15.5570	15.9709
Silver-content, ounces.....	6.6072	6.7041
Zinc concentrate, tons.....	37,333	45,194
Zinc in concentrate, per cent...	52.928	52.9956
Zinc in concentrate, pounds.....	39,519,432	47,901,445
Silver in concentrate, ounces...	21,500	21,8757
Recovery, per cent.....	93.314	92.989
Mining costs per ton.....	\$4.9437	\$4.4971
Milling cost per ton.....	\$2.1691	\$1.7610

The decrease in quantity of ore treated during the last term was due to an accident in the shaft in August, thereby causing the suspension of operations for 11 days. The increased cost in mining and milling is due

rate dividend was paid on September 30 together with an extra of \$5 per share.

Financial results showed the following:

	Third quarter	Second quarter
Net value of zinc concentrate at mill....	\$1,731,670	\$2,879,568
Net value of lead concentrate at mill, etc.	190,099	246,341
Miscellaneous income.....	14,757	22,772
Total net value.....	\$1,936,527	\$3,148,682
Operating cost, etc.....	988,625	1,086,653
Profits.....	\$ 947,901	\$2,062,029

Copper Output in September Quarter

Reports of several copper companies for the third period of 1916 are to hand, and include the following information:

	Chino	Nevada Con.	Ray	Utah Copper
Overburden moved, yards.....	961,617	1,585,963
Cost of mining, cents per ton.....	78.46
Ore treated, tons.....	801,500	1,020,546	849,100	3,404,300
Average per day, tons.....	8,712	11,093	9,233	37,000
Copper-content, per cent.....	1.89	1.68	1.571	1.4484
Concentrate, tons.....	62,531
Copper-content, per cent.....	16.48
Recovery, per cent.....	61.94
Cost of milling, cents per ton.....	54.99
Total copper, pounds.....	20,606,723	24,585,393	19,061,727	61,079,924
Cost, cents per pound.....	8.17	8.67	10.348	6.322
Price for copper, cents.....	25.61	23.883	27.722	25.364
Total income.....	\$3,445,292	\$3,901,197	\$3,299,100	\$12,049,460
Dividends paid.....	1,957,455	1,999,457	1,182,884	4,873,470
Surplus for period.....	1,487,837	1,901,740	2,116,516	7,175,990

to the smaller tonnage treated, the constantly increasing cost of supplies, and the larger maintenance costs brought about through repairs to the Black Rock shaft.

The average price used in estimating returns on spelter for the quarter is 8.3441 cents per pound. The directors voted to increase the regular dividend rate from 75 cents per share per quarter, to \$1.25 per share, at which

Increases in production were 2,507,511 lb. by Chino, 494,372 lb. by Nevada Con., 394,063 lb. by Ray, and 12,684,995 lb. by Utah Copper. Dividends were the same in the last two quarters by Chino and Utah Copper, increases of \$199,505 and \$394,295 being paid by Nevada Con. and Ray. The amount of copper on hand, if any, is not stated.

New Scheelite Discovery

By W. H. STORNS

A new tungsten region was discovered during the past summer on the west slope of the Greenhorn mountains, in Kern county, California. One of the discoveries is near the head of Cedar Creek canyon, on the middle fork; the other is about two miles south, on Slick Rock creek, near the road between Glenville and Kernville. The region is mostly granitic, but includes several elongated areas of much altered Paleozoic sedimentary rocks, principally argillite, quartzite, and limestone. These areas are usually several hundred feet wide and 2 to 3 miles long. Along the borders of the granite and the old sediments there is often a broad zone of metamorphism, in which garnets, epidote, hornblende, secondary silica, and some other minerals are abundant. It is in these zones of metamorphism that the tungsten mineral occurs, in the form of scheelite. Neither wolframite nor hübnerite were observed at either of the places where prospecting had been done. Several holes had been sunk at various places in the district in rocks similar to those described where no tungsten was discovered, though in some of these holes veins of solid pyrite, 5 to 7 ft. thick were uncovered.

Whether these zones of contact-metamorphic minerals represent an alteration of what were originally masses of limestone, I do not know, not having had the time or opportunity to examine thoroughly the localities far from the prospect-holes that had been sunk in search of tungsten. At one place I found a zone of metamorphism nearly 100 ft. wide, consisting mostly of several varieties of garnet; a felsitic dike had been intruded into this mass and in the felsite were a few crystals of molybdenite, but no scheelite or other tungsten mineral was seen.

In the prospect holes near the head of Cedar Creek canyon, scheelite was liberally sprinkled through the garnetized mass, assays ranging from a trace up to 30% WO₃. Many of the crystals of scheelite were the size of large peas, but no solid masses of the mineral were found. The zone of garnet at this place was apparently at least 25 ft. wide, but so little work had been done and the surface outcrop was so obscure that the actual width could not be determined.

At the other locality, on Slick Rock creek, the scheelite was also associated with garnet, together with hornblende, black tourmaline, feldspar, quartz, a little pyrite and chalcopyrite, and with an abundance of pyrrhotite. This latter mineral is an unusual accompaniment of tungsten minerals as far as I have observed or heard. This hole, I was told, was originally sunk in prospecting for tin, years ago, but no tin was found. The ore, like that on Cedar Creek, was of good grade, running from 1 to 30% WO₃, but the amount of development was negligible. The vein was apparently but three feet wide, with a wall of mica schist on one side and a granitic rock on the other. It stood nearly vertical, striking

northwest-southeast. Two zones of fissuring crossed the vein at a right angle, each forming a zone of crushed material about a foot wide. These fissures were 10 ft. apart, having this small segment of good ore between them. There was no trace of scheelite in either of these cross-fissures, nor in the vein itself at or near the surface, where the sulphide minerals had been oxidized, forming a limonite cap or gossan. Evidently the sulphuric acid, freed by the oxidation of the sulphide minerals, had dissolved the scheelite, and the tungstic acid had been completely removed by leaching. However, at two or three feet below the surface the scheelite began to appear in the form of much corroded sandy crystals, which at a little greater depth were firm, well defined, and glassy. It is scarcely likely that these two discoveries are the only occurrences of tungsten in that region. Others doubtless will be found by persistent search. The district is in direct line with the tungsten belt known to extend from the vicinity of Raymond, in Madera county, south-eastward to the vicinity of Atolia, in Kern county. Along this belt tungsten ores are known to occur at a number of places between the limits indicated, though it is by no means improbable that the 'belt' will be found to extend in both directions far beyond Raymond at one end, and Atolia at the other.

In the granite areas of this region are also known veins of antimony ore, principally stibnite and jamesonite, and also veins of gold and silver ores. Pegmatite, diorite, and other intrusions are numerous in some places, penetrating both the granite and metamorphic rocks, and the geological conditions are favorable for the formation of veins. The region is heavily timbered, water is abundant, and good automobile roads cross the mountains at intervals of every few miles.

In the early days of mining in California there was an important gold region in the vicinity of Kern River canyon, and many gold mines were then developed and worked with varying success, much of the ore being high-grade. A revival of mining in this region, on both sides of Greenhorn mountain is not at all improbable, which will be stimulated somewhat by the prospecting for tungsten ore, which is likely to be carried on vigorously next summer. Winter work is entirely feasible in a camp fully established and equipped, but surface prospecting during winter is handicapped by a heavy snowfall. The altitude of the tungsten camp is about 6500 feet.

NICKEL PRODUCTION OF Canada, which means Ontario, this year is estimated to total \$23,000,000, against \$20,123,318 in 1915, and \$13,655,381 in 1914. Over 80% of the world's output comes from the Dominion, mostly from the Sudbury district. Three large companies are operating, namely, the International Nickel Co., the Mond Nickel Co., and the British-America Nickel Corporation, a new concern. The first named reduces the ore to matte at Sudbury, refining in New Jersey; the second makes matte at Coniston, Ontario, refining at Clydach, Wales; while the new company will probably reduce the ore in Ontario.

COPPEROPOLIS, LOOKING NORTH.

THE CALAVERAS COPPER CO.'S MILL.

Flotation at the Calaveras Copper—A Simple Flow-Sheet

By Hallet R. Robbins

INTRODUCTION. The Union mine is situated in the foot-hills of the Sierra Nevada in the extreme southern part of Calaveras county, California. The town of Copperopolis, with a present population of about 600, has grown up around the mine, and is reached by road from Angels Camp, 12 miles; Stockton, 42 miles; or Milton, 17 miles. The mail is carried by automobile-stage daily except Sunday over the last route, and there is also regular auto-stage service from Stockton. Surveys have just been completed, and construction is about to be started, on an extension of the Southern Pacific railroad from Milton to Copperopolis, two views of which are shown at the top of this page.

This is one of the oldest and most interesting metal mines in California. It was discovered by placer miners in 1859, and soon afterward one portion of the lode was acquired by Frederick Ames of Boston, and another, called the Keystone mine, by Oliver Ames. The Union Copper Mining Co., organized by the former, subsequently absorbed the Keystone property, as well as several smaller holdings on other portions of the lode. Operations were conducted by the Union Copper Mining Co. on a large scale. During each of the years, 1865 and 1866, about 23,000 tons of ore, averaging over 20% copper, was shipped to Swansea, by wagon to Stockton, by river-boat to San Francisco bay, and finally by sailing-vessel around the Horn. A stone blast-furnace was erected and operated on second-class ore averaging 10% copper, using charcoal as fuel. The matte was shipped to Swansea. No statistics are available as to the tonnage treated in this smelter.

The fall in the price of copper following the Civil War, as well as the high cost of transportation, caused the mine to be closed-down in 1867, in which condition it remained until 1887, when there was a renewal of activity at the property, culminating in the erection, in

1891, of another blast-furnace smelting-plant, which ran about two years, and produced 150,000 tons of slag.

Operations were again suspended in 1893, the mine remaining idle until 1905, when a gravity-concentration mill and a third smelter were built. The mill did not run longer than a week or two at this period, but the smelter ran about two years on first-class ore. Heap-roasting was practised, the calcine being smelted in a 50 by 7 ft. reverberatory furnace, producing a 50% matte, which was shipped to a refinery at Chicago.

The panic of 1907 caused another suspension of operations, lasting until 1909, when the Calaveras Copper Co. was organized and took over the property on a bond. The smelter was re-built, and two 20-ft. six-hearth McDougall roasters were erected. The plant proved unworkable after two weeks' trial, and then a 40 by 120-in. blast-furnace was built, but it ran for two weeks only. Converting equipment was purchased and delivered, but never installed. The mill was operated intermittently at this time, but did not make over a 50% saving.

In September 1914 a capable and efficient manager in the person of S. M. Levy, of Salt Lake City, was appointed, under whose guidance, with the assistance of E. C. Trask, mill foreman, D. C. Williams, mine foreman, and Frank W. Royer, consulting engineer, the property has been firmly placed on a paying basis, and has become one of the greatest promise.

THE OREBODY is a replacement in amphibolite schist; it is from 100 to 200 ft. wide, with slate hanging wall and serpentine foot-wall. The valuable minerals are chalcopyrite, containing no gold or silver, and, near the surface, red and black oxides of copper. The lode is free from serious faulting, it strikes north-west, dips 61° north-east, has been fully developed for a length of 1500 ft. and to a depth of 800 ft., and is known to persist over a length of three-quarters of a mile. There is every

indication of persistence in depth, as well as to a greater distance along the strike.

The most striking peculiarity of the ore is the association of a large amount of barren pyrite with the chalcopyrite. This is the explanation for the many failures to exploit the mine, for when gravity concentration was attempted, the pyrite was saved, while the chalcopyrite was largely slined and lost.

THE MINE is opened by two working-shafts, the Union and the Discovery. The former is 800 ft. deep, vertical to the 5th level, and on an incline of 63°, following the lode, from there to the bottom. It was sunk in the 'sixties, and is equipped with a wooden head-frame, 35 ft. high, and with a double-drum hoist with both steam and electric drive.

The Discovery shaft is in the lode, on the hanging-wall side, and is now 400 ft. deep, measured along the 61° incline, but is being connected with the 9th level by raising. It is equipped with an excellent steel head-frame, 80 ft. high, erected in 1902 at a cost of \$10,000, and good for four compartments, though the shaft now has but three; and with a steam-driven double-drum hoist, good for 1500 ft., and with a 1500-cu. ft. compressor driven by a 275-hp. motor.

The stopes are 15 to 30 ft. wide; the shrinkage method is followed, at a cost of 50 cents per ton. The total cost of mining, including timbering, hoisting, development, etc., with the present daily production of 200 tons, is \$1.50 per ton. It is expected that this will be reduced to \$1.25, as soon as the production is increased to 500 tons per day, which is the maximum output expected at present.

The force employed includes 2 shift-bosses at \$4; 10 machine miners at \$3.50; 4 timber-men at \$3.50; 4 timber men's helpers at \$3.25; and 22 shovellers at \$2.75.

Ingersoll-Rand stopers are used for stoping and raising; jack hammers for sinking and block-holing; and Denver Drednought water drills in the drifts.

The mine is considerably wetter in winter than in summer. In the wet season, one 1½ by 7 in. triplex pump is operated 24 hours daily, raising all the water made by the mine, from the 8th level to the surface. In the summer it is run only six to seven hours per day.

FLOTATION. Experiments began in December 1914; in February 1915, the so-called little mill was started on accumulated tailing from the old gravity mill, containing about 1.5% copper. The equipment consisted of one Huntington mill, grinding through 50 mesh, a mechanical agitator, a pneumatic flotation cell, making a final tailing and a rough concentrate, and a Wilfley table, making a final concentrate and a middling that was returned to the Huntington. In May 1915, the treatment of accumulated tailing was discontinued, the 'little mill' after that date handling 25 tons per day of undersize from the 4 in. trommel at the pitting plant. The oversize, after the first class ore had been picked out, was treated in the 'big mill,' which was the old gravity mill with some experimental flotation equipment, handling 60 tons per day, with much the same flowsheet as in

the little mill, so that further description is not necessary.

The results of this operation indicated that from a mill-feed assaying 3% copper, 28% iron, 20% sulphur, 20% silica, and 10% alumina, there would be obtained a concentrate assaying about 19% copper, 30% iron, 35% sulphur, and 6% insoluble, with a ratio of concentration of 7:1, and a recovery of 90%.

These operations also indicated that the most efficient oil was Yaryan steam pine-oil, and that mechanical agitation of the pulp before flotation was necessary for the best results.

The old gravity-mill, which was housed in a well-built and substantial steel-frame building, was then further re-modeled, and in March 1916 operations began according to the flow-sheet shown in Fig. 1. These operations have been remarkably successful.

PRESENT PRACTICE. The extreme simplicity of the plant, and the entire absence of any gravity concentration are very striking. The ball-mill has a normal capacity of about 8 to 9 tons per hour. The reduction in one mill from 3-in. size to a product 90% of which passes 80-mesh would not be economical in a large plant, but in a small one the simplicity of the arrangement is commendable. The mill is driven through a counter-shaft, by a 150-hp. motor, at a speed of 23 r.p.m. The normal power consumption when running is 120 hp. Forged steel balls, 5 in. diam., are used, the consumption being 0.5 lb. per ton of ore ground. Of the total product 40% is finished through 80-mesh, the remainder being returned by the classifier. The mill has given reasonable satisfaction, the most serious difficulties being blinding of the difficultly-accessible grating, leakage around lining-bolt holes and dropping-out of lining-bolts, and a peculiar ailment, not as yet fully diagnosed, but probably due in part to the wear of the lining, that at times has caused the capacity of the mill to drop practically to zero. When the mill was opened on such occasions the ore and balls were found in quite separate masses. Increasing the speed from 21 r.p.m., as recommended by the makers, to 23 r.p.m. proved beneficial in minimizing this trouble.

Difficulty has also been encountered in the buckling of the lining segments, which are the full length of the mill, thicker on one edge than on the other, in order to form steps to lift the balls and cause them to cascade properly through the charge of ore. They are held by three bolts in a line along the centre of each segment. The edges of the segments draw away from the shell, and the lining requires to be discarded and renewed when only about half the metal has been worn away. Similar troubles have been reported at other plants, and it is my belief that they may be overcome by the use of lining in full annular sections, wedged in place, with no bolt-holes whatever through the shell. Such sections may be secured from the Lehigh Car Wheel & Axle Co., and are being tried by the Utah Copper company.

The oil adopted as standard in the present operation, after exhaustive experiments, is the No. 400 crude wood-

erosote produced by the Pensacola Tar & Turpentine Co. The No. 350 crude pine-oil produced by the same company was recently tried on a 24-hours run, with a marked increase in the value of the tailing, and a decrease in the grade of the concentrate. A mixture of equal parts of No. 17 hardwood-erosote, and No. 20 coal-tar erosote, furnished by the General Naval Stores Co., has given the best results of any oil other than that regularly used.

The oil is all fed into the ball-mill feed-box from a

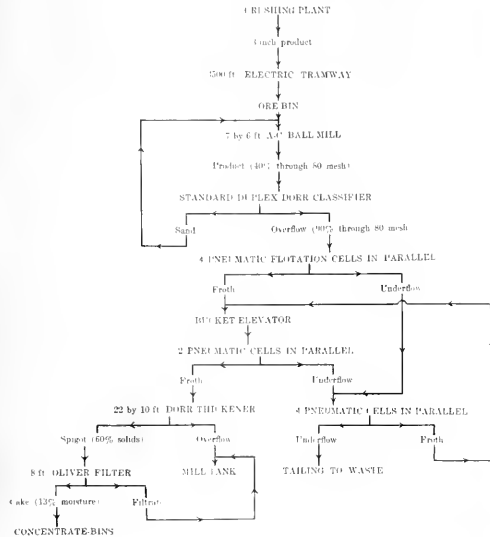

FIG. 1. FLOW-SHEET.

15-gal. zerolene can, fitted with a special bronze stop-cock. The consumption averages 0.3 lb. per ton of ore. It is so well mixed and agitated in the ball-mill that neither mechanical nor pneumatic agitation before flotation is found of any benefit whatever.

The return of the filtrate from the concentrate-filter, and of the overflow from the concentrate-thickener has been found not only to decrease the amount of oil required, but also to effect a closer saving than is possible otherwise, no matter how much oil be used.

The flotation-cells are made locally from Oregon fir, protected with P. & B. paint, at a cost of about \$100 each, complete. They are of the type for which J. M. Callow has had process and apparatus patent applications pending in the United States for some time. The porous bottom differs from that used by Mr. Callow in the cells he has built. It is composed of eight separate shallow cast-iron pans, placed side by side along the sloping bottom of the cell, each covered with a multiple-canvas, fastened around the edges only. Screens or grids, similar to those used by Mr. Callow were tried but proved both unnecessary and objectionable.

The outside length of each pan is a trifle less than the inside width of the cell. Two $\frac{3}{4}$ -in. pipes are screwed into

FIG. 2. COPPEROPOLIS AIR-PANS.

the bottom of each pan, and pass through holes bored in the wooden floor of the cell. One is connected by means of an easily-removable length of hose, to the air-main manifold, and the other is fitted with a plug-cock, nor-

FIG. 3. THE MILL.

mally closed, but opened periodically to blow out accumulations of water in the pan.

When it is desired to remove a pan, the air-hose is disconnected, and the plug-cock unscrewed, when the pan may easily be lifted from the cell. When the cell is

in operation, the holes through which the air and water-blow-off pipes pass, are caulked with oakum. This form of air-pan was an original development at Copperopolis, but resembles that developed originally at McGill, Nevada, and used in the pneumatic flotation-cells of the Nevada Consolidated Copper Co. A photograph of two of the Copperopolis air-pans, one right-side up and the other bottom up, is shown in Fig. 2.

A detail drawing of the flotation-cell as a whole, from which one may be built by any competent carpenter, is shown in Fig. 4.

Air is furnished at $5\frac{1}{2}$ lb. pressure by a Connersville blower. The consumption is about 80 cu. ft. free air per min. per cell. Each cell is emptied once per day and the surface of the canvas is washed off with a hose. The canvas lasts several weeks, and when a renewal is necessary, it is effected quickly by removing the pan in the manner described, and replacing it with one already freshly clothed.

The air-supply is not filtered, but I believe it is good practice to do so in all cases where porous media are used in flotation-cells. During the past two years I have visited nearly every flotation plant of consequence in the West, and have seen no pneumatic cell frothing so smoothly and evenly as those at Copperopolis.

Some interesting experiments have been made in heating the thickened concentrate in the filter. At some plants where this has been tried, it was found possible to make a cake of double or treble the usual thickness, with no increase in the moisture content. This is probably due to the heat decreasing the viscosity of the oil in the pores of the filter-canvas.

The results of the operation of the plant may be appreciated from the following assays of composite samples for the month of June 1916:

	Copper, %	Iron, %	Insoluble, %
Heading	2.15	20.4	37.0
Concentrate	11.40	29.5	14.9
Tailing	0.09	18.0	43.4
Rough concentrate	8.0
Cleaner tailing	2.0
Ratio of concentration, 7.1			
Saving of copper, 26.4%			
Saving of iron, 30.2%			

It will be interesting to compare these results with those obtained in the old gravity mill, the concentrate from which assayed 5.8% copper, 35.5% iron, 37.4% sulphur, 12.7% silica, and 6.5% alumina. The heading ran 2.1% copper, the tailing 1.5%, the ratio of concentration was 6.6:1, and the percentage of recovery of the copper was 50.

At present the tailing normally assays a 'trace,' which means not over 0.01% copper, a remarkable record, but I believe that any ordinary chalcopyrite ore may be treated by a similar method with similar results. I have myself made a mill run at this plant with an ore containing 1.38% copper as chalcopyrite, and 22% iron, mostly as pyrrhotite. The grade of the concentrate was 7.32% copper, the tailing 0.07%, the ratio of concentra-

tion 5.53:1, and the recovery 95.9%. I have in mind two plants operating under license from Minerals Separation, treating simple chalcopyrite ores, that do not contain nearly so much pyrite as the Calaveras ore and therefore should be much easier to concentrate. Each of these plants uses a more complicated flow-sheet than the Copperopolis plant, and is proud of a tailing containing 0.15% copper. This is eloquent evidence concerning benefits accruing to licensees of Minerals Separation from the superior (?) metallurgical knowledge placed at their disposal by that syndicate.

OPERATING COSTS. These are shown by the following figures taken at random from the company's books, representing actual costs for the week ended July 7, 1916:

Power, 184 hp. per day, at 0.825c. per kw.-hr.....	\$191.25
Operating labor, 70 shifts, at \$3.25.....	228.75
Superintendence, repair, and extra labor.....	137.48
Supplies of all kinds	132.40
	\$689.88

On a normal tonnage of 192 per day, this is equivalent to 51.4c. per ton.

TRANSPORTATION. Incoming supplies and outgoing concentrate are hauled between Milton and Copperopolis by wagon with trailers, drawn by 14 horses, and carrying about 12 tons per load, at a contract price of \$3.25 per ton, or about 20c. per ton-mile. The road is very rough, and attempts to use auto-trucks have resulted in failure thus far. During the rainy season the condition of the road is so bad that it is impossible to do any hauling; it has been necessary even to suspend operations during that period. Rail-freight on the concentrate is \$1.25 per ton from Milton to the smelter on San Francisco bay, and \$6.40 per ton to Tacoma, where this product is now shipped.

PICTURE OPERATIONS. There has just been installed an 8-ft. by 30-in. Hardinge ball-mill on trial, under a guarantee by its manufacturer that it will grind 25% more ore, with 25% less power than the 7 by 6-ft. Allis-Chalmers mill. It should be remarked, however, that the price of the Hardinge mill is \$1800 more than that of the Allis-Chalmers.

It is the intention of the Calaveras management to make careful competitive tests of the two mills on the same ore, and under identical conditions. It is hoped that the results of these tests may be presented to the readers of MINING and SCIENTIFIC PRESS by E. C. Trask, in the near future, if the Editor will risk hurting the feelings of one of his advertisers, and it is believed that the figures will be of value to all those interested in ball mills.

The two ball mills together, whether operated in series or in parallel, are expected to have a capacity of about 500 tons per day, and 10 additional flotation-cells, with the necessary blower, are being installed to take care of the increased tonnage. The present Oliver filter (8-ft. diam. by 6-ft. face) is to be supplemented by one of the same face but 11½ ft. diameter. This is expected to

handle 50 tons per day of thickened concentrate, reducing the moisture to about 12%, with a cake half an inch thick.

It is proposed to convey the concentrate from the thickener to the filter in a 5-in. pipe through the centre of which there will be a 1-in. steam-pipe. This will avoid diluting the thickened concentrate-pulp by condensed steam.

It is estimated that no more labor will be required to operate the plant when treating 500 tons than at present. Assuming the power and supply costs to increase propor-

tionally with the tonnage, an average weekly cost would be approximately as follows:

Power, 479 hp. per day, at 0.825c. per kw.-hr.....	\$497
Labor, as at present	366
Supplies	690
	<hr/> \$1553

This is equivalent to 44.4c. per ton, but it is believed the actual cost will not exceed 40c. On the completion of the railroad, the capacity of the plant may be still further increased by the installation of a third ball-mill, for which room is yet available in the old mill-building.

The total capital expenditure for converting the old gravity-mill into a highly-efficient flotation-mill of 500 tons daily capacity will be less than \$50,000. A new mill built according to this flow-sheet should not cost much, if any, more, as the figure noted includes the net cost of considerable experimenting, and the dismantling of the entire equipment of the old mill, amounting to as much as a new building would cost under ordinary circumstances.

Without wishing to draw invidious comparisons, it is interesting to note that the National mill in the Coeur d'Alene, built to treat 500 tons per day of a simple

chalcopyrite ore, cost \$153,000, and has never made so close a saving as the Calaveras plant, and cost about the same to operate as the latter with its present small capacity of less than 200 tons per day. Of course, much less was known about flotation when the National mill was built than today.

Messrs. Levy and Trask are modest as to their achievements, but rumors of the excellent results they have accomplished have traveled widely, and the plant has been a Mecca for metallurgists from all parts of the country. Each visitor has departed with a pleasant impression of

FIG. 4. DETAILS OF FLOTATION-CELL.

the courtesy with which he was received and the freedom with which all desired information was made available.

COPPER ORES occur in beds of sandstone, both red and gray, in Utah, Arizona, and New Mexico. Some of the deposits are of considerable magnitude and commercially valuable. In New Mexico several of these unusual copper deposits have been worked on a commercial scale and have afforded, in the aggregate, a large amount of copper, though usually the deposits are small and low-grade. The copper occurs primarily as chalcocite in small disseminated grains which oxidizes to malachite and azurite, and to a less extent to cuprite. The deposits of New Mexico, which have thus far proved to be the most valuable, occur in the Red Beds (both Triassic and Permian) and usually at no great distance from underlying crystalline rocks—granite and schist of pre-Cambrian age, in which copper occurs. These copper-bearing sandstones are not in the least metamorphosed, even by the infiltration of secondary silica, and they are not intruded by igneous rocks of any description. Often they are practically undisturbed by folding, nor have they been crushed or altered to a condition unlike that of the other strata with which they are associated.

Strontium Nitrate: A New Industry

By Donald F. Irvin

The active efforts made in sundry branches of the mineral industry, such as tungsten, potash, and the metals used in the ammunition trade, do not cover the entire field of opportunity created by the War. There are other products, hitherto almost unknown to the public, that have increased several hundred per cent in price: an example in point being strontium nitrate, which is produced from the mineral celestite, strontium sulphate, and is used as a necessary ingredient in pyrotechnics.

The valuable property of this chemical is the intense red color it produces in fireworks or signals. A large part of the total annual production is used in the manufacture of railway signal-fuses and marine signals, a railway-signal company being the largest single consumer in the United States.

While in no sense an explosive, it decomposes quickly, and is subject to a high risk-rate in warehouse-charges.

Prior to 1914, the American market for this chemical was dependent mainly upon European sources, and prices at New York were about 8 to 8.5 cents per pound. How large a proportion of the total business was done at that price it is difficult to ascertain.

The total consumption in the United States is stated, on good authority, to have averaged above 5 tons daily, and since the commercial complications wrought by the War, the price, *f.o.b.* New York, has mounted rapidly, until in June 1916, the figure quoted in trade journals was nominally 40 to 50c. per pound.

This figure, in common with those for other high-priced War commodities, is not 'pegged'; it denotes hope rather than accomplishment. The high quotation represents the purchase of less than ton lots by consumers in a small way, to meet their immediate needs, and is not a criterion of the prices that govern transactions on a larger scale. These prices, representing the actual return to the manufacturer, are the only basis for the true estimation of the possible profit.

A recent investigation of the manufacture of strontium nitrate in Southern California disclosed two new plants using local raw materials on a small scale.

References to the metallurgy of strontium, as made by Thorpe, Watt, and other authorities, concern themselves chiefly with the production of strontium hydrate, which is widely used as a clarifying agent in the beet-sugar refineries of Europe. Strontium salts are made cheaply in Europe, where there are widely distributed deposits of the more desirable strontianite, as well as celestite, the sulphate.

Clarke's 'Data of Geochemistry' mentions the occurrence of celestite in the great saline deposit of Stassfurt, Germany; it is also interesting to note that it is found at Searles lake. Hence the small local enterprises above-

mentioned were based upon the improvisations herein described, and did not attempt to emulate the elaborate practice of the large and long established European reduction-plants.

It is evident that the limited possibilities of consumption, and the fact that the increased price is due to transient conditions, does not induce substantial investment. Amortization rates should be high, as a measure of prudence. The 'reducing-balance' method of calculating depreciation, as described by R. S. Lewis in a recent issue of the MINING AND SCIENTIFIC PRESS, is hardly rapid enough to provide for a sufficient writing-off in this case.

Bulletin 540-T of the U. S. Geological Survey enumerates various deposits of celestite in the Western States, and one of these (at Ajo, Arizona, near the New Cornelia Copper Co.'s mine) supplied ore for one of the nitrate plants at Long Beach, California. The other plant, at Los Angeles, obtains its ore from Southern California, out of a deposit not mentioned in the Bulletin quoted. This deposit is in Imperial valley, about 40 miles by wagon-road from the Southern Pacific Railway, and therefore involves wagon or motor haulage.

Like most celestite deposits, this orebody was the result of precipitation, and is underlain by gypsum; in fact, it is said to have been first located for the sake of the gypsum itself. Mining methods are extremely simple, as the ore is removed from the surface without more labor than picking up the broken fragments with which it is strewn. The ore is finely crystalline, generally white, and on fresh fractures has an almost pearly lustre. Its high specific gravity considerably reduces the volume of material handled, per ton treated, as compared with ordinary ores of silicious character.

Methods of treatment at both of these plants are essentially the same, as the Long Beach plant derived its methods from the Los Angeles plant, which is some months older, and the same general description will suffice for both. The essential steps involved are the reduction of the sulphate to the sulphide; dissolving of the sulphide, and the nitration of the sulphide solution, forming strontium nitrate solution, which is then evaporated.

The first step is most important, and likewise most difficult; the factors affecting it are not entirely at the ready control of the operator, nor are unfavorable ones quickly recognized. Reduction is performed by the action of finely powdered carbon in the presence of heat.

Apart from the proper choice of a furnace, it is necessary to have an easily regulated fuel, and temperature-control is indispensable.

Dissolving of the sulphide, the second step, would be

simple, if the reduction were complete, as there would then be a completely soluble charge, and no residue to wash. As it is, there is always a considerable amount of unaltered celestite in the furnace charge, which must be separated from the pregnant solution, obtained by the digestion of the roasted ore.

The result of dissolving the strontium sulphide in water produces not only a sulphide, or sulph-hydrate solution, but also, a precipitate of hydrate crystals, which are re-soluble only at a high temperature. While this affords a convenient way to remove rapidly a part of the strontium from solution, it is also a nuisance in that crystallization occurs upon and in everything prior to arrival at the proper stage for removal, and much care is needed to prevent the crystals from mingling with the discharged residue and clogging the pump-lines, in the further course of the process. Jacketed pipe-lines and a supply of live steam when needed will avoid much of this trouble.

As is customary in leaching processes, the end-washes of one cycle, which are low in dissolved material, may be used to make up the first decantation on the next cycle, and the water needed to make up the bulk lost by evaporation is added as the last decantation.

In the end, all solutions are sent to the nitrating-tank, and the washed residue from the furnace-charge, after solution is effected; much reduced in amount and with a small loss in dissolved value (which is chiefly due to its small bulk, and not to specially good technique) is stacked.

Filtration in the accepted sense, including washing of the cake, is not practised; possibly, because of the small quantity handled.

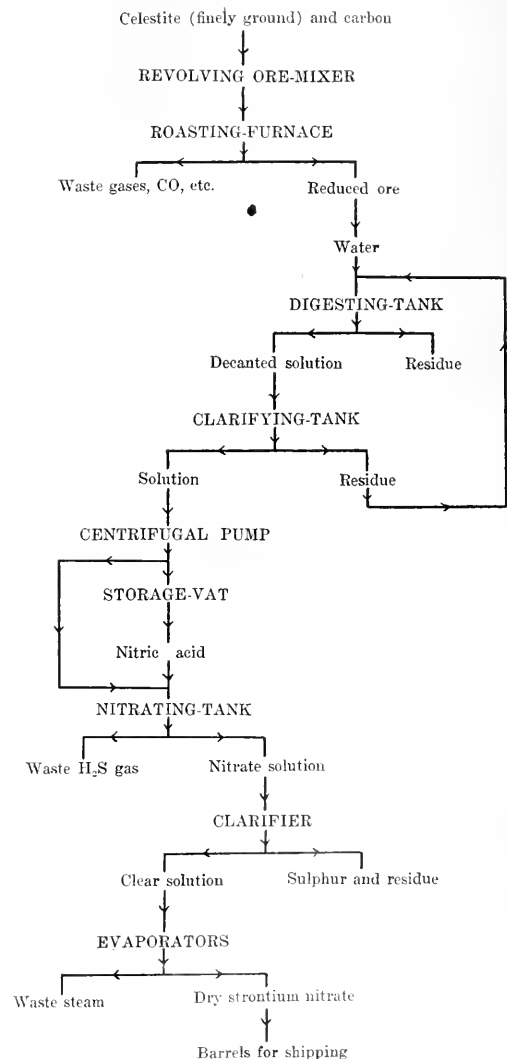

Nitration is effected by direct use of nitric acid and is accompanied by a steady and copious evolution of H_2S ; the disposal of this objectionable and harmful gas has been the subject of various expedients, which have succeeded in eliminating the bad effect upon the workmen and decreasing the complaints made by residents in the vicinity.

The lid of the nitration-tank was provided with a water-seal, after the manner of a gasometer, and the gas was drawn therefrom by a suction-fan, which discharged it through a pipe outside the building. At the point of discharge, is a small pilot-light, whose function is to ignite the H_2S as it reaches the air, burning it to SO_2 . The latter gas causes less complaint by the neighbors than when H_2S was discharged.

The nitrate solution is clarified after acid treatment, removing any extraneous material and any free sulphur that may have separated out during nitration, and then the clear solution is evaporated in open vats. No vacuum-pans are in use; chiefly because of the small size of the operations, but they would undoubtedly be much more effective than the open pans now in use, as regards economy of fuel and time. The reduction in temperature also would tend to prevent overheating of the nitrate, which is decomposed at a comparatively low temperature. When open pans are in use, it is well to dry over a steam-

or water-bath. The dried salts are screened and packed in wooden barrels for shipment, providing against injury from moisture.

Comminution of the crude ore is done in a custom-milling plant at Los Angeles, the process requiring tube-

FLOW-SHEET. THE WATER AND NITRIC ACID JOIN THE MAIN LINE OF FLOW FROM ASIDE.

milling without use of water. The extraction obtainable, as in most metallurgical operations, is affected by the scale of the work and the choice of equipment, as well as the general process. In the method described, on a nominal rating of 1 ton of ore treated in 24 hours, the net extraction may reach 70% of the possible. In this connection, it must be remembered that the chemical re-

actions alter the weights of the strontium salts derived from the original unit of celestite.

or 100% extraction of strontium nitrate, represents 1.14 times the weight of the original celestite, and 70% extraction on a ton of celestite would be: $2000 \times 1.14 \times 0.70$, or 1596 lb., which is 79.8% of 2000 lb.

Occasionally higher extractions than those mentioned have been observed, but are not frequently obtained in the routine of operation; without doubt, a net extraction of 75 or 80% could be obtained with adequate equipment.

While there is much which, to the casual glance, may seem crude and ineffective in these small plants, second thoughts reveal the underlying intent to achieve a profit in the least possible time, while incurring the least financial risk.

Unstable market conditions, of unknown duration, do not justify substantial equipments or the refinements of processes found in modern concentrators or cyanide plants, which are based upon large and persistent ore-bodies.

After all, since mining and ore-reduction is a commercial affair, conducted for purposes of profit, a scheme of treatment that involves loss in residue, and which is foreign to the trained metallurgist's conception of 'good practice,' may really be highly economical in the end. This observation is trite, but always worth repetition, when considering the number of costly and unprofitable reduction plants, the failure of which has been due largely to the neglect of this very principle.

The calendar has confuted so many amateur and professional forecasts on the duration of the War that any observations on this subject are dangerous. Yet upon this duration depends the measure of prosperity that is possible for the mineral industries that have been specially fostered by War conditions. It is a reasonable belief that serious competition on the basis of antebellum prices is not practicable where the costs due to raw materials, labor, and freight to market are as high as they are for the Californian strontium nitrate plants. The largest single item of cost is that of acid, and a substitute for that reagent would mean great economy. This would appear to be attainable if it were feasible to use crude sodium nitrate in a decomposition role. A similar plan is said to be in use in European nitrate plants, but details are not known. Even if the theoretical details were suitable for a small plant, this method would not be commercially feasible, owing to the difficulty of completely and economically removing the highly objectionable sodium content, which affects the color of the flame of the firework or signal.

The same difficulty prevents a successful commercial application of the use of soda ash in the reaction

with subsequent nitration of the carbonate by nitric acid.

This method is attractive in its apparent simplicity, which avoids the need of roasting, and is mentioned in

Bulletin 540-T, but the complete removal of sodium is attended with so much difficulty and expense, that it cannot be seriously considered in a small plant. Repeated and careful washes with distilled water fail to remove the sodium or to prevent the sodium-yellow from masking the strontium-red in the color of the flame.

Assuming that after the War, prices will resume their former level, which is of course, a debatable point, it is reasonable to foresee, meanwhile, possibly a year of satisfactory business for the nitrate plants. Those already established, with an assured supply of satisfactory ore and well-designed plants should by that time have been able to amortize their modest capital charges and amass a reasonable profit, if their selling agencies have been well chosen; an equally important condition.

THE superintendent, T. W. H. Shanahan, of the Mint at San Francisco reports the following business during October:

Bullion received:		
Gold	Fine ounces	Value
Australian gold	5,039.981	\$ 104,185.65
Sovereigns	235,377.738	4,865,689.69

Total	\$427,248,291.03

IRON PYRITE in zinc sulphide concentrate is a nuisance, and the U. S. Bureau of Mines at Salt Lake City has devised a process to remove the interfering mineral, as follows: The method consists of treating the mixed sulphides in a reducing atmosphere at 600° C. The pyrite loses one atom of sulphur under these conditions and is reduced to a form that will react with dilute sulphuric acid, while the zinc sulphide is resistant to the acid. In this way the iron can be removed, making a marketable zinc product.

Smelting at Anyox and Grand Forks, B. C.

In the annual report of the Granby Consolidated Mining, Smelting & Power Co. for the year ended June 30, 1916, the superintendent of smelters, W. A. Williams, gave the following details concerning the plants that reduced a total of 1,929,205 tons of ore:

The second year of operation at the Anyox plant shows a decided improvement over the preceding period.

The works operated 1,167.43 furnace-days out of a total of 1414. On account of power-shortage during the winter months 141 furnace-days were lost, on account of ore-shortage 2 days, smelter strike 11 days, mine strike 5 days, making a total of 159 furnace-days lost for reasons not attributable to smelter troubles. An average of 3.2 furnaces out of four was in blast.

On the lower or tapping-floor a great many problems, incidental to handling a large tonnage of corrosive-molten material, have been solved, which has all tended toward the lengthening of campaigns. The molten material dealt with aggregated 250,000 tons.

The charging-system was changed this year to Anaconda type charge-cars, which dump the ore into pockets, the charge being pushed into furnaces by plows operated by compressed air when needed. This has been a decided improvement over the old method, and has been the chief aid in extending the length of campaigns.

No. 4 furnace, which has a shaft depth 5 ft. greater than the original furnaces, was operated 10½ months. It was watched carefully to see if the increased depth was an improvement. There seems to be no gain in the grade of matte, increased tonnage, or percentage of coke used; however, there does seem to be some gain in the length of campaign, and reduced crust formation due to the increased drop of charge. For this reason, if another furnace is erected, it will be made the same as No. 4, but there is not sufficient advantage gained by the increased depth of shaft to warrant changing the old furnaces to conform to this height.

In the smelting of Hidden Creek ores an effort was made to keep to the proper proportion of No. 1 and 2 orebodies, both as to quantities and analyses. As regards tonnage, there was smelted approximately equal parts of No. 1 and 2 ores, but these were a little low in silica. The average of the total orebodies will be somewhat higher in silica than the average analysis for the year 1915-'16. As regards copper-content, the ores are about the average of the whole body.

The conclusion was arrived at that true pyritic smelting cannot be done with the main ores as was done at first, that is, with low coke and no fluxes. This can be done at times, but not frequently enough to say it is the practice. The proportion of free SiO_2 is small, most of it being present as combined silicates. The Al_2O_3 is also high, and will probably exceed in the total orebodies the average for this year. It is necessary to use fairly high coke and limestone as flux. So far, the ores coming to the smelter have varied greatly in the silica-content from

lot to lot. This has created a tendency to uneven running, and necessitated a slightly greater quantity of coke and flux than would have been used otherwise. There is no remedy for this condition until the mine is opened more, or until such time as a sorting-table and screening-plant are installed.

It has not yet been feasible to make a converter grade of matte in the first smelting operation, as the degree of oxidation is low, and the matte-fall from the ore smelting is too great for the converters to handle. Therefore, one furnace was used practically throughout the year as a re-grading furnace, which means that three furnaces were operated smelting green ore, while the fourth was used for re-grading matte. The better method would be to take all the matte straight to the converters, irrespective of grade, and convert direct. This would increase the tonnage of green ore, and tend to lower costs all around, and, at the same time, help recoveries. The reason that this practice is not being followed at present is lack of converter-capacity.

The quantity of ore per furnace-day has increased from 630 to 692 tons, and total charge from 846 to 929 tons. During the year, 88,853 tons of foreign ore was smelted, which means that one blast-furnace was used 35% of its time for the total year in the smelting of this ore to the exclusion of Hidden Creek ores, and that higher cost of mining resulted, due to a lesser tonnage shipped from the company's mines. There is 46,480 tons of flue-dust stored awaiting the installation of a sintering-plant.

No changes have been made in the converting department. The converters operated steadily, with the exception of the five winter months, during which time they only worked 57 out of 152 days on account of lack of power. Additional converter-capacity is needed in this department.

The cost of smelting and converting was \$1.804 per ton of ore. This is 73c. less than in the previous year, but it is higher than was anticipated. The increase in wages, due to the rise in price of copper added 4.57c. per ton of ore. The use of about 20,000 tons of barren quartz in the re-grading and converting of matte (used on account of the scarcity of metal-bearing quartz) added 68c. per ton of ore. At the present time an endeavor to take care of this is being made with the opening of the Maple Bay properties. Lime flux added 15.2c. to the costs. Ore carrying excess lime would be advantageous in reducing this cost. The shipping of 21,428 tons of matte to the Grand Forks plant for conversion into blister-copper, on account of power shortage, added 2c. per ton of ore. Coke was a few cents higher on account of quality and handling in and out of storage, due to the irregularity of vessels' schedules caused by strikes of longshoremen. This added 1c. to the costs. Owing to the War, all supplies advanced 10% over normal prices. This meant an addition of 4c., making a total increase of 33.5c., the greater part of which amount will be eliminated in time.

During the past year there was considerable new work

that was found necessary to charge to operation, such items as fire protection of the 6-ft. water-pipe from the dam to the power-house, the railroad trestles, some agglomerator charges, new roof for main smelter-buildings, ore-bin extension, and charge-cars.

It is reasonable to expect a reduction in costs during the coming year. Ore costs would have been 6c. less had the profits made by the different departments, operating as independent concerns, been credited back. Another large item of expense which shows against costs for the past year is auxiliary power supplied for five months during the winter. The new steam-plant now under construction will take care of this heavy expense, and allow of operating to capacity throughout the coming winter. The sintering-plant, when installed, will take care of the flue-dust, and increase the recovery of copper.

Operations at the Grand Forks smelter were characterized chiefly by the handling of nearly 500,000 tons of material that was low in copper, about 1%, and highly silicious. Up to the present time this material has not

been calculated in the ore reserves, but on account of the high price of copper which has prevailed during the past year it became profitable to treat it. This partly accounts for the high costs of that period. However, for the first six months of the year costs were the lowest in the history of the plant, being \$1.233 for smelting and converting.

Owing to the high price of copper, the increase of wages added 1.7c. Coke was 1.3c. higher per ton of ore, due to the silicious nature of the ore. Anyox matte added 0.7 cent. The slow running of the furnaces, due to high-silica slags, offsets the increase of this year's costs over last year.

With eight furnaces in blast, there were from 195 to 200 men on the pay-roll.

There was no new construction during the year, but repairs have been maintained, and the plant is in first-class operating condition.

Credit is due W. B. Bishop, the superintendent, and the staff under him, for the good work done.

Flotation in the Supreme Court

The U. S. Supreme Court now has before it the appeal of Minerals Separation from the decision of the U. S. Circuit Court of Appeals in San Francisco in the litigation against J. M. Hyde, who represents the Butte & Superior Mining Company.

The complainant's brief states: "The distinctive feature of the invention patented is the employment of air bubbles in co-action with a minute and critical amount of oil in a mixture of ground ore and water so as to produce upon the surface of the water a froth containing substantially all of the metallic particles which can be easily flowed off or removed. This process was never used before. This result was never obtained before. The process is dependent upon the use of oil in a minute and critical amount and thorough aeration. If more oil is used, you do not operate the process, and you do not get the result.

"By using other and greater quantities of oil you operate a different process and you obtain wholly different results. That the critical amount of oil characterizing the process is a minute amount of oil (varying slightly with different ores and different oils) is merely a fortuitous circumstance. Nevertheless the process is dependent upon such definite minute amount of oil. Obviously, therefore, it cannot be said that the use of the minute amount of oil characterizing the process in suit as compared with prior disclosures suggesting the use of greater amounts of oil, is a mere improvement in degree suggested by the desire to economize in the use of oil, since every prior disclosure with which the process may be compared was wholly different in characteristics and essential mode of operation and principles involved and result obtained. The process of the patent in suit evokes new principles, employs a new mode of operation, and produces a new result, not heretofore evoked, employed or produced."

In argument for the defendant Hyde it was pointed out to the Court that "all flotation processes fall into one of three distinct classes: (1) The Elmore bulk oil or oil buoyancy flotation process; (2) the surface tension of film or skin flotation process; and (3) the gas-oil flotation process. The process * * * (involved) belongs to the third class, wherein the flotation is due to the buoyancy of bubbles of air or other gas." The defendant's argument states that "upon the subject of air the patent in suit contains only a single statement, wherein it is asserted that the froth or scum derives 'its power of flotation mainly from the inclusion of air bubbles introduced into the mass by the agitation. * * *'. Surely, no patentable discovery is involved in the observation of the obvious fact that a froth or foam floats by reason of the air in the bubbles of which it is formed and in any event, patentable novelty cannot be predicated upon a theory as to the cause of an old effect in the absence of some new means for producing that effect."

Relative to the amount of oil used the defendant's counsel argued that "the patent in suit contains no suggestion that the process can be practised with a 3.6% or 25% of oil relative to the ore. The patentees knew that such a statement would prevent them from obtaining a patent; therefore in order to make it appear that they had discovered something new they made the statement to the effect that the formation of a froth or scum grew out of and depended upon the use of a smaller amount of oil than used by Cattermole."

The Hyde counsel concluded their argument with the submission of a statement "that the decree of the Circuit Court of Appeals should be affirmed on each of the following grounds: That the patent in suit is anticipated and invalid; that all of the claims of the patent of which infringement is charged * * * are anticipated by each of the following processes, Everson, Froment, Schwarz, Glogner, and Kirby; and that those claims which do not specify the use of acid * * * are anticipated by the Haynes British patent."

Electrolytic Zinc-Dust

By Harry J. Morgan and Oliver C. Ralston

*The sudden increase in the price of zinc-dust after the beginning of the European war, owing to the cutting off of the German and Belgian supply, led to some experiments on the possibility of producing the dust on a commercial scale from solutions of zinc, and the substitution of the zinc made in this manner for the zinc-dust ordinarily used in the precipitation of gold and silver in the cyanide process.

As the Salt Lake City station of the U. S. Bureau of Mines, in co-operation with the Department of Metallurgical Research of the University of Utah, is carrying on investigations that have for their object the treatment of low-grade and complex zinc and lead ores or products, it was thought well to determine whether the zinc contained in such ores and products could not be utilized in the manner above indicated, and so supply the demand that had arisen for zinc-dust.

The United States, in 1913, imported 4,382,470 lb. of zinc-dust, valued at \$227,585. Most of this was from either Germany or Belgium. The domestic production, in comparison with the imports, was very small. In the years 1912 and 1913 the domestic production was 492 and 423 tons respectively, while the imports were 2400 and 2200 tons respectively. For a time the zinc-dust made in zinc smelters was a drug on the market and when first utilized in cyanidation could be bought for a lower price per pound than solid zinc. After the advantages of the use of zinc-dust for precipitation were realized, so much of it began to be used for this purpose that it brought a premium of about 3 cents per pound over what the value of spelter was at the beginning of the War. Since that time its price has averaged about 30c. per lb., without much fluctuation. Some American zinc smelters have undertaken to supply the demand, but their product has never been equal to the German zinc-dust.

Experiments were made by Morgan¹ in the application of a jet of air to atomize a column of molten zinc for making the dust. This work was conducted at the Bureau of Mines exhibit at the San Francisco exposition, but the zinc-dust was not satisfactory for cyanide precipitation. While it was fine enough to pass a 200-mesh screen, it was only 25% efficient in the precipitation of

silver from cyanide solutions and a microscopic examination showed that the small pellets of zinc were in the shape of congealed droplets, which present a minimum of surface for reaction with the silver cyanide solution. This idea has been further carried out at Anaconda and we are informed that 10 to 15 tons of atomized zinc is now being prepared per day, in preference to sponge zinc made by electrolytic deposition from sulphate solutions. This dust is being used for purification of zinc-sulphate solutions, for the reason that the more finely divided electrolytic sponge tended to clog up the Schriver filter-presses used at that plant.

To us, a better idea seems to be the making of a zinc sponge by electrolytic methods, the sponge to be of such a nature that it would crumble to dust when dried. The variety of electrolytic conditions available, with the different electrolytes that can be used, and the resulting great differences in the physical properties of the precipitated metal, gave promise of the possibility of a zinc-dust that would be highly efficient and rapid. As a result of experimental work, it is believed that this possibility has been realized. In addition to its use for precipitating gold and silver from cyanide solutions, zinc-dust can also be used in sherardizing, and for chemical purposes, such as reduction of organic compounds, etc. Sherardizing requires a considerable proportion of relatively coarse particles of zinc, similar to the atomized zinc above mentioned, but it is possible that the manufacture of dyes and other such chemicals in the United States can create a considerable demand for electrolytically prepared zinc-dust of high purity and efficiency. The following work was done with a view to preparing a product satisfactory for cyanide practice and does not consider the needs of the sherardizing industry, or of the chemical industries.

According to Sharwood,² zinc-dust for use in cyanide precipitation should be fine enough so that 90% of it will pass 200-mesh and it must be high in metallic zinc. A considerable amount of zinc oxide may be present without seriously affecting the efficiency of precipitation. The following method of testing the efficiency of precipitation by zinc-dust is given by Sharwood: After passing the dust through a 100-mesh screen to break up the lumps, 303 mg. is weighed out and added to 250 cc. of 1% silver-cyanide solution containing 0.15% free cyanide. The solution is stirred occasionally for two hours, after which it is withdrawn from the precipitated silver by filtration. The precipitated silver is dissolved in nitric acid and titrated with ammonium sulpho-

*A paper read at the recent meeting, at New York, of the American Electro-Chemical Society. By permission of the Director, U. S. Bureau of Mines. Communicated by D. A. Lyon, Metallurgist in Charge of Salt Lake Station of Bureau of Mines.

¹In this work Morgan was assisted by R. H. Bradford, Professor of Metallurgy, of the University of Utah, and under the direction of G. H. Clevenger, Professor of Metallurgy at Stanford University.

²*Jour. Chem. Met. Min. Soc., So. Africa*, VII, 332 (1912).

cyanate, using a ferrie salt as an indicator; or else the precipitated silver is scorified and cupelled to be weighed. Each milligram of silver precipitated represents 0.1% efficiency of precipitation. This test is merely an empirical one of general acceptance, admittedly near enough to allow of intelligent buying of zinc-dust. It is stated by Herz that the efficiency of zinc-dust should be over 40% and that dust with less than 30% efficiency generally gives poor results. Dust of over 50% efficiency is hard to obtain. The average grade of zinc-dust from Europe is 15% efficient, but in this work we have been able to get dust giving an efficiency of 74%.

The usual endeavor of the zinc hydro-electro metallurgist is to obtain solid reguline deposits of zinc rather than the sponge, as the sponge metal can rarely be melted into spelter. The literature on electrolytic zinc is full of instances where work was stopped on account of the 'tendency' of the zinc to be deposited in a spongy form. However, we found that, in duplicating this work and following the conditions as given, there is only a *tendency* and that the average result of such conditions is trees, warts, or loose crystalline zinc. We found as much difficulty in obtaining a true sponge as the beginner usually finds in getting smooth solid deposits. Conditions of high-current density and low-current density, high acidity and low acidity, or basicity, high temperature, etc., were tested and it was hard to get all the sponge that others had reported as being so easily obtained.

We have been informed that one metallurgical company produced several thousand pounds of zinc-dust in its electrolytic zinc plant at Welland, Ontario, by allowing the temperature of its solutions to go up above 70° C. and that it was used by one of the local firms with indifferent success. The electrolytic plant in question is operating a sulphate solution of zinc in which ore is suspended in the solution while the cathodes are protected by bags. Most of the sponge or the loose crystals prepared by us from sulphate solutions did not possess a high precipitating efficiency. Spongy zinc was formed when solutions of zinc sulphate containing dissolved zinc oxide were used, but as soon as the solutions became acid, owing to the formation of sulphuric acid at the anode, the zinc lost most of its spongy characteristics. An excess of zinc oxide suspended in an open cell is not desirable, as it mixes with much of the loose zinc sponge formed. Removal of the solution to an outside vat, for treatment with zinc oxide, is not desirable on account of the slow, and low solubility of the zinc oxide in the zinc sulphate solutions.

The method of adding impurities to the solution was tried in order to get spongy zinc. Copper and arsenic were found to be most efficient for this purpose, but copper is not a desirable constituent in zinc dust on account of its presence in the precipitate of the precious metals. Arsenic is also undesirable in the precipitate, if the lat-

ter is to be treated with sulphuric acid before melting into bullion, owing to the formation of poisonous arsine. All the copper was found to be deposited quickly from solution with the sponge zinc, but after the deposition of the copper, the zinc deposits began to be more solid and crystalline. A continual drip of copper sulphate into the electrolytic vat is hence necessary. The addition of iron as an impurity did not result in producing successful sponge zinc. Furthermore, the oxidation and reduction of iron salts at the electrodes lowers the current efficiency.

The favorable results obtained in solutions made slightly basic encouraged the use of basic solutions of zinc, such as sodium zincate. The zincates allowed a wider latitude in the precipitation of zinc sponge than any other solutions tested. Lead anodes tend to dissolve, and zinc anodes dissolve almost quantitatively. Iron anodes are practically unaffected, especially those made of the better grades of iron. After doing this work it was discovered that practically the same idea had been patented by Sherard Cowper-Coles in British patent No. 13,977 of 1907. The electrical conditions best for this work are not mentioned by him, but we find that a wide range of voltages is allowable, and most of our work has been done at a current density of about 300 amp. per sq. ft. (3225 amp. per sq. m.). Cowper-Coles mentions the possibility of using galvanized "hard zinc" for anodes when making sponge zinc, as the iron is not dissolved, while the zinc is, thus lowering the operating voltage and replenishing the solution. He also recommends the use of a rotating vertical disc for a cathode, a form of cathode which we had adopted after some considerable test work. The disc can be made of iron and the upper half projects out of the electrolyte. The sponge is scraped off the disc into water as the disc slowly revolves. Rapid rotation of this disc is not allowable, as the better agitation of the electrolyte causes the formation of adherent zinc, which defeats our purpose. To have a barely perceptible motion of the disc is sufficient. We had anticipated trouble in the drying of the dust, but met with none, as we found it could be heated to 250° C. on the hot plate in the open air without ignition. The washing of the sponge free from the adhering solution of sodium zincate must be performed with weaker caustic, as the zincate hydrolyzes in water solution to zinc hydrate and sodium hydrate. A water-wash can follow a caustic soda wash. The dust prepared in this manner was highly efficient (over 70%).

LARGE-TIN SMELTERS in the world are in the Straits Settlements. One, that of the Straits Trading Co., has a capacity of 35,000 tons per year; the other, of the Eastern Smelting Co., treats 17,000 tons. The Dutch Government smelters produce 15,000 tons. Capacity of English plants is 28,000 tons. Germany can reduce 11,200 tons, and the A. S. & R. Co. at Baltimore in its new plant is smelting 3500 tons. Australian smelters make 35,000 tons per annum. These figures refer to metallic tin.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

CONDITIONS IN THE ZINC REGION DURING OCTOBER.

Returns from the Wisconsin zinc region for October, from the 1st to the 25th, inclusive, scarcely reflect the healthy conditions that prevailed during the period. At the beginning of the month the markets were not entirely satisfactory from the miner's point of view, standard and premium grades of zinc ore holding on a base of \$60 per ton, with the range down to \$50 on second and medium-grade ore. Shrewd buying interests, knowing that prompt metal was becoming scarce and that better prices might be anticipated, skillfully secured a large proportion of the output by entering into contract arrangements for ore on long terms. The Eagle-Picher Lead Co. of Joplin, Missouri, bought heavily of high-grade material before advances in the price of zinc ore had really set in. These advances materialized as the month went on, standard and premium grades commanding a base price of \$70, with second and medium grade at \$65 per ton base. At these figures buying became active, and high-grade ore was cleaned-up at all points, while a freer movement of medium-grade ore set in that affected the low grades, much of which had lain in bins for many months. The reserve in the field at the beginning of the month, estimated at 5000 tons, has been reduced to 1500 tons, and this would be eliminated on short notice.

An acute shortage of labor developed in the southern districts of the field, which operators found it difficult to meet. The final closing-down of four consistent producers, throwing 250 men out of employment failed to relieve the situation, as ready employment was offered each man at near-by producers. Production failed to come up to expectations, the recovery of crude concentrate for the month aggregating 18,000,000 lb. It was considered that better offerings would stimulate producers to exert themselves to meet the better demand and better offerings, but in this view many were disappointed. It was held in many quarters that producers keenly scented better market conditions through the winter months, and preparations were made for an increased production when the time was ripe. This led to greatly increased labors in underground development, additional installation of buildings and machinery while the weather was good, and the rushing of work to get new mines with new surface outfits into working order. All this was accomplished during the month, and will be appreciated in the better showing in output throughout the remainder of this year. Facilities for handling crude concentrate at zinc-ore refineries were somewhat enhanced, and in addition plans were laid for the early construction of a new plant at Whitson Junction, a connecting point on the Northwestern railway well removed from settlement, as sentiment at several points in the field had developed against refineries because of the nuisance from fume. In the Galena district this reached a critical point, the city authorities serving notice on one of the large companies to abate the nuisance or close-up the plant.

Lead ore was in good demand all the month at greatly improved prices, but producers showed little interest in the market, and shipments were light. Offerings toward the end of the month were in excess of \$85 per ton, but the bulk of the ore was held closely and the reserve in the field was well on toward 1000 tons.

Shippers of pyrite enjoyed a better demand, and more tonnage was disposed of, but a fairly good reserve was still held

at the close of the month. The acid department of the New Jersey Zinc Co.'s plant at Mineral Point showed increased activity, and one 25-ton tank-car of commercial sulphuric acid was sent out daily.

Producers of carbonate of zinc ore experienced an exceedingly poor month. Prices for this ore are kindred with quotations usually published for calamine ores. At the close of October, in sympathy with the higher prices for blende, price had advanced to \$45 per ton, 40% base; but Wisconsin producers went begging for a market until well along toward the close of the month, when outside buying interests stepped in and cleaned-up several hundred tons, with the immediate prospect of taking all such ore as local producers had to offer. Such shipments as were made came from the mines of the New Jersey Zinc Co. in the northern districts of the field.

Several new producers commenced at eight different points in the field; five producers shut-down indefinitely. There were in course of construction new plants at four different points, and mine development was noted in every district of the field. Drilling operations were extensive, especially for the larger operators.

Deliveries of ore of all grades for October were as follows: 45,254,000 lb. of zinc, 766,000 lb. of lead, and 6,408,000 lb. of pyrite.

The Mineral Point Zinc Co. delivered 5,232,000 lb. of high-grade refinery product to smelter at DePue, Illinois. The total shipments of high-grade ore out of the field from refinery plants to smelter direct totaled 12,790,000 lb. The heaviest outside buyer for the month was the Grasselli Chemical Co. of Cleveland, Ohio, with 3859 tons. The Eagle-Picher Lead Co. came next with 1728 tons.

SUTTER CREEK, CALIFORNIA

LABOR SITUATION.—CENTRAL EUREKA TO SINK.

Within the past week, a large number of Spaniards have come to Jackson, Sutter Creek, and Amador City, most of whom are finding employment in the mines at Jackson and the South Eureka property here. The Fremont company is also adding some of these men to its pay-roll, being shorthanded since the strike. Most of the companies have their mills in full operation, but local miners resent the fact that the Fremont, South Eureka, Kennedy, and Argonaut companies pay less than the general scale of wages for certain work, and are also discriminating to some extent against the leaders in the recent strike. This doubtless accounts for their requiring the services of outside men.

Preparations are almost completed for sinking the Central Eureka shaft far enough below the 3200-ft. station to allow for two new levels. At present this is the lowest point worked in the mine, although the shaft sump is nearly 75 ft. below that station. The engine heretofore used at the 2800-ft. winze has been installed at 3100 ft. in the shaft, and at this point will be dumped all the rock and waste from shaft-sinking; this material to be used for filling stopes, instead of its delaying mining operations by being hauled through the shaft. A bulkhead will be put in the shaft for the protection of men working below, and rapid progress can be made when sinking is started within the next few days. It is expected that at least half of the 40-stamp mill can be kept working steadily while sinking is in progress, as fair grade ore is being mined on the 2800, 3000, and 3100-ft. levels.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

In Bulletin 631 of the U. S. Geological Survey, H. M. Eakin discusses the Yukon-Koyukuk region, in 88 pages. The area embraces 12,000 sq. miles in central Alaska, between the Yukon and Koyukuk rivers. The predominant topography is rolling uplands. Winters are long and cold. Game is generally abundant. Steamers ply on the rivers during the open season. Alluvial gold is widely distributed in the region, but save those of the Indian river the deposits have so far shown little economic importance. There are no gold lode mines.

ARIZONA

BISBEE. Three companies—The Louisiana-Arizona, Bisbee

DETROIT COPPER CO.'S MILL AND SMELTER, MORENCI, ARIZONA.

Copper, and another are to start exploration of the copper-bearing area outside of the Warren district. Sufficient capital is said to be interested in these schemes.

GRONK. A crosscut on No. 11 level of the Arizona Commercial has passed through 50 ft. of ore, 15 ft. of which is high grade, the remainder concentrating ore. On No. 10 level the hanging wall side of the vein is a sulphide assay 25% copper. Six feet of siliceous concentrating ore contains 3.5%.

PHOENIX. At the third annual meet, held on the 14th, the Old Dominion team won the mine-rescue contest, with Calumet & Arizona second, and Detroit third. C. & A. won the first-aid event, followed by Old Dominion and Ray Consolidated, who tied.

YUCCA. In the Bulletin of the Chamber of Mines and Oil of Los Angeles, F. L. Wilson briefly describes the tungsten deposit near this place, which is 32 miles north-east of Topock in Mohave county, and 16 miles south-east of Needles. Pegmatite dikes cut a belt of schist, limestone, and quartz. Wolframite is the principal tungsten mineral. Copper occurs nearby. Molybdenite is found in the Hualapai range, east of Yucca, in quartz veins cutting granite and schist.

Sixty-five tons of ore containing 39.26% copper was the last shipment from the Grand Gulch mine in Mohave county to Utah smelters. Salt Lake City people control the property, which has a peculiar orebody. Dividends this year total 4c. per share, equal to \$10,000. This mine, which has an ore deposit of circular shape, was described in the Press of July 11, 1914.

CALIFORNIA

DOWNIEVILLE. The Morning Star and London Tunnel mines are to be re-opened by Los Angeles people, and supplies are now being sent in.

(Special Correspondence.)—The Allison Ranch company is about to construct its mill and cyanide plant. Excavation is complete. The head-frame is almost finished. Excellent headway is being made in unwatering the mine. The Golden Center company will start shortly excavating for its new cyanide plant. C. A. Brockington is in charge of both of these properties, and F. A. Vestal is consulting metallurgist.

The Delhi mine has been unwatered and the mill is being overhauled for early resumption of milling. R. E. Tremoureux is in charge.

The Indiana Dredging Co. has taken a lease on several miles of creek at Greenhorn valley, a few miles from this town. They are sinking shafts, and contemplate constructing a large dredge. D. H. Ferry is in charge.

A new 5-stamp mill is being erected at the Mariposa mine, a short distance from Alleghany. This property is one of the promising quartz mines in the district.

The North Star company continues improving its plant. Grass Valley, November 13.

GRASS VALLEY. The Union Hill, Gold Point, and South Idaho mines are to be consolidated by the company that recently purchased the first-named. The main shaft is being sunk from 800 to 1200 feet.

LA POINTE. The concrete retaining dam on Slate creek, constructed to permit of hydraulicking at St. Louis and Howland Flat in Sierra county, is practically complete.

MEADOW LAKE DISTRICT. This region is in the eastern part of Nevada county, and indications point to a busy season next year. The Old Man Mountain and other claims of H. D. Ramsey have been sold for \$101,000. A number of small properties have been actively worked with favorable results.

RIDGING. To drill for oil near Buckeye, the Pacific Oil Co. has been organized with W. Wolfe of San Francisco as president.

(Special Correspondence.)—The Harvard mine, near Jamestown, which has regularly employed 100 or more men for a number of years past, has suspended operations. Whether

there is likely to be an early resumption of activities cannot be stated with any degree of certainty, nor has anyone with authority announced the cause of the shut-down.

The California Gold Mining & Development Co. has secured an option on the Chaparral mine, south-east of Tuolumne, from F. A. Wenzel, of Sonora. It is understood that the company has also acquired several adjoining properties. A Sullivan air-compressor and machine-drill will be purchased, and it is expected that the drift will be driven at the rate of 10 ft. per 24 hours.

Electric power and water have been brought to the Red Jacket mine, at Big Oak flat, and the small mill on the property was started recently. So far the ore crushed has given highly satisfactory returns.

The working crew at the Springfield Tunnel & Development Co.'s deep-gravel property was recently reduced to three or four men. Active work underground will, it is said, be resumed before long. Meanwhile prospecting with a Keystone drill will be done to ascertain the exact course, depth, and richness of the several gravel-channels.

The Columbia Basin gravel mine, whose shaft is 200 ft. deep, is being unwatered preparatory to the resumption of operations.

The flotation plant being installed at the Dutch mine will be given its initial trial within a few days. Extensive development work has been done since W. J. Loring assumed management, and some valuable discoveries have been made, among which may be mentioned the opening of a fine orebody below the 1800-ft. or bottom level, by means of a winze, now 130 ft. deep.

Harris Bros. & Moore have started sinking a shaft on the Ben Soulsby ranch, near Soulsbyville. It is expected that at a depth of 40 ft. the vein, which gave high assays in other shallow workings, will be encountered. A gasoline engine and centrifugal pump have been installed.

A contract has been let for sinking the shaft at the Garfield 100 ft. and driving a drift 200 ft. The property recently changed hands.

The shaft at the Columbus mine, north of Tuolumne, has attained a depth exceeding 300 ft. Good ore shows in the shaft almost from top to bottom, and the management is elated over the results of development thus far. Thirteen men are on the pay-roll.

Sonora, November 14.

(Special Correspondence.)—W. J. Loring has taken an option on the Harvard mines on the Mother Lode, a mile west of this town, the papers having been signed on the 16th. The mine has been idle for a short time pending a preliminary investigation.

Jamestown, November 17.

(Special Correspondence.)—One after another of the old mining properties of Tuolumne county are being re-opened, and the prospects for greater activity in mining than for several years is promising.

At the Red Jacket mine in the Big Oak Flat district the mill is running three shifts on good ore. Electric power is being used to run the mill and compressor. This mine but recently began operations and the outlook is bright.

While plowing on his farm near Columbia, William Rhem unearthed a \$100 nugget. It was found near Springfield flat, which produced many millions in the early days.

The flotation process at the Dutch-App group of mines will soon be in operation. It is being watched with much interest by many mining men of Tuolumne county, as this is an innovation in gold-ore treatment here.

The old Bonanza mine, in the centre of Sonora, is soon to be re-opened. This mine has produced over \$2,000,000 in pocket gold, and is expected to soon be on the producing list again. It has been bonded to J. B. Curtin and George Weston of Sonora.

Sonora, November 12.

COLORADO

LEADVILLE. Pumping commenced at the Harvard shaft of the U. S. S. R. & E. Co. last week, and unwatering should be finished in a short time.

A 300-hp. electric hoist, the largest in the State, has arrived at the Mikado shaft. The pumping equipment has not been delivered so far.

TELLURIDE. During the year ended June 30, 1916, the Tomboy Gold Mines Co. made a profit of \$379,000. Two dividends absorbed \$140,000. After paying English taxes and depreciation the balance was \$95,000. The mill treated 150,488 tons of ore, yielding \$1,074,080. The average cost was \$4.92 per ton. Reserves in the Argentine mine are 175,000 tons; in the Montana 400,000 tons, a total of 575,000 tons.

IDAHO

ADAIR. According to H. M. Lancaster, recently superintendent, the Richmond mine contains over \$1,000,000 of ore ready for extraction in the two upper levels. A recent car-load averaged 15.5% copper.

HAILEY. The new 150-ton mill of the North Star-Triumph claims is nearly complete. The Federal Mining & Smelting Co. controls the property.

KELLOGG. During the quarter ended September 30, 1916, the Caledonia Mining Co. made a profit of \$296,390. Development is being carried on in the Keating tunnel-level in an effort to recover the faulted orebody, but so far without success. The work is being continued, however, and the area in which it is thought that the lost shoot will be found is to be thoroughly explored. The metal output was 2,652,600 lb. lead, 350,422 oz. silver, and 220,681 lb. copper. Cash, ore on hand, and in transit, etc., is \$375,366 net.

LOON CREEK DISTRICT. The Lost Packer copper mine in Custer county has been closed for the winter, the usual procedure on account of transportation difficulties. The 50-ton mill, using flotation, recovered 90% during the season. P. Sheahan is manager.

MULLAN. According to George Huston, geologist of this place, three questions are interesting mining people in the Coeur d'Alene: (1) the entrance of the Anaconda Copper Co. into zinc-ore buying, (2) how lower development in the Interstate-Calahann mine will result, and (3) the status of the National copper mine, near Mullan.

PINE CREEK DISTRICT. The Coeur d'Alene Antimony Mining Co. has increased its capital from 500,000 to 1,500,000 shares, 10c. par value. Investigations are being made into the treatment of ore, and the production of metal or oxide. The mill can treat 100 tons of ore daily. A large tonnage of ore has been developed.

MISSOURI

JOPLIN. Prices for zinc ore were \$10 per ton higher last week, the range for 60% product being from \$75 to \$90. The output of the Missouri-Kansas-Oklahoma region was 7664 tons of blende, 832 tons of calamine, and 612 tons of lead, averaging \$2.50, \$47.50, and \$87 per ton, respectively. The total value was \$718,068.

The deputy State mine inspector, J. H. Myers, considers that sanitary and protective measures are being increasingly observed by operators in the Joplin district.

MONTANA

BUTTE. On the 2500-ft. of the Davis-Daly mine the '2501' vein has been opened 500 ft., with 15 ft. of ore still in the face. For 450 ft. the average over a width of 12 ft. was 57% copper, also 1.6 oz. silver with each unit of copper.

In its north-west adit the North Butte company has cut 18 in. of sulphide ore assaying 3.25% copper and over 2 oz. silver per ton. This development is in the eastern part of Butte.

The Butte-Detroit company is to treat zinc ore for the Davis-

Dal. company, while the Anaconda company may treat the ore concentrate at Great Falls.

According to H. N. Knowlton, of the U. S. Forest Service, 20% of the total cost of mining is for timber used.

The report of the Barnes-King Development Co., which operates in Ferguson county, shows that during the third quarter of 1916 the profit was \$6457. The revenue from gold-bullion was \$107,887. Total income was \$203,037, which included balance from June 30, power-plant earnings, royalty, and notes payable. The Shannon mine made a profit of \$23,606, the North Moccasin and Piccan-Gloster mines losses of \$7089 and \$8684, respectively. Considerable expenditure was made in improvements and payments for properties. In October 3360 tons of ore yielded \$77,550.

CRINOID. In this district of Missoula county, F. G. Bond has discovered rich bismuth ore. The vein is in quartzite and granite.

NEVADA

GOLDFIELD. The Jumbo Extension company is to prospect with a core-drill through the shale and into the alkali.

Owing to the copper-gold ore in the Florence being too low grade, treatment has been suspended and the mine closed. In treating 200 tons daily by flotation the process was quite satisfactory.

A raise above the 880-ft. level of the Jumbo Junior is in good ore near the Kewanas boundary.

GOODSPRING. Estimates of reserves in the Bullion mine give at least 12,000 tons of 12% lead ore for the 125-ton mill. There is also a good deal of shipping ore opened.

LAS VEGAS. Platinum has been detected in the Eldorado Enterprise Gold Mining Co.'s property in Eldorado canyon. Rich gold-silver ore has been opened in the Carnation claim. A stamp-mill and cyanide-plant are proposed by lessees of the Lombard claim.

(Special Correspondence.)—At a depth of 20 ft. rich ore has been intersected on the Lombard claim by Charles Herman, M. Fisher, and James German. The ore assays \$1000 per ton in gold and silver, and was discovered near the Carnation claim, the scene of a good strike two weeks ago.

The shaft of the Cliff Era is down 155 ft., and is being sunk 200 ft. in expectation of intersecting a large vein that has been traced on the surface for 4000 feet.

Ore of good grade is showing in the shallow workings of the Eldorado-Empire, and arrangements have been made to sink the shaft to considerable depth. A compressor, drills, and other machinery have been purchased.

Representatives of San Francisco capitalists are examining several mines in the Eldorado Canyon field, and a number of important deals are stated to be in course of negotiation. San Francisco people are in control of the Enterprise group, and are opening good ore.

Searchlight, November 12.

NEW MEXICO

(Special Correspondence.)—The Socorro M. & M. Co. shipped 23 bars of bullion from the claim up for the last half of October, a total of 41 bars, or a little over two tons for the month, from the treatment of 5000 tons of ore. The product of the Mogollon Mines Co. for second half of the month was 12 bars, making 25 bars for October, worth 4100 tons. In addition, several tons of concentrate was shipped to smelter at El Paso.

The Oals Company's 125 ft. cut of ore to bottom mill from exploratory work in the Clinton mine gave \$14 per ton. The ore came from the Queen vein.

At the Gold Dust prospect, on which work was lately resumed, the main adit is under consideration of retreating, and raises and drifts are being extended.

Earl C. Cleveland, who, as we have been reporting, has data relative to hydrocarbon gas or possibilities in this region, has just returned from the oil fields of the Gila river,

where he and others have run surveys and taken water readings over a period of two years. So far the average flow found, under available head, if sufficiently developed, will take care of both present and prospective power requirements of the district. When some such project is consummated Mogollon will be able to treat profitably an almost unlimited quantity of low-grade ore that otherwise is unavailable under present high-power costs.

Mogollon, November 7.

TEXAS

(Special Correspondence.)—The recent resumption of copper mining in the lower part of the 'Panhandle' region of Texas recalls one of the most magnificently equipped and spectacular expeditions that was ever sent out to extract metal from the earth, having for its object mining of copper in the same area where the work has been again started under more modern auspices. In 1881, the Grand Belt Copper Co. was organized by G. B. McClellan, a general during the Civil War, who found copper there years before. The New York capital behind the company bought 250,000 acres of land, supposed to embrace the deposit. Gainesville was then the nearest railroad point, a 75-mile haul. The miners were mostly cowboys. Mining operations were more like digging prairie-dog holes than anything else. Large 'modules' of copper were gathered at times, two carloads being shipped East. There was much buying of shares on the strength of this ore. No defined vein could be found during six years' work. A 10-ton smelter and 20-ton stamp-mill were erected. It was not then possible to extract the copper from the clay. Finally the company collapsed. Thousands of ore-sacks and machinery were abandoned to be taken by farmers and others. The one improvement, in Knox county, was a good flowing artesian well, 4000 ft. deep, and said to be flowing yet.

Austin, November 4.

(Special Correspondence.)—The Southwestern Mining Co. is developing a lead-zinc, silver mine near here. It has been making regular shipments of ore to the smelter for some time past. In the 300-ft. level a large body of ore that is high in lead and zinc with about 50 oz. of silver per ton was encountered.

Sierra Blanca, November 11.

(Special Correspondence.)—The West Texas Sulphur Co. is preparing to exploit two large sulphur deposits that it owns near here. It will install retorts for the treatment of the sulphur-bearing material, and a plant for refining the product.

Toyah, November 11.

UTAH

ALTA. Daily shipments from this district are from 100 to 125 tons of first-class ore, mostly from the South Hecla and Michigan-Utah. Good progress is being made with the new railway from Wasatch to Alta.

At the Wasatch Mines property the open-cut, which goes below the proposed new tunnel, is 1000 ft. long. On account of loose gravel the tunnel has not been started yet.

BINGHAM. The Montana-Bingham tunnel is in 4300 ft., the daily advance being 15 ft. with two shifts. The face is in quartzite.

The Utah Consolidated will pay \$1.50 per share on December 20, a total of \$150,000, and \$1,125,000 for the current year.

DUNN. This old district, 23 miles west of Oasis on the Salt Lake Route, is busier than for years. The ore is mainly copper-bearing.

PRIOR. Twenty miles south-west of this place the Copper Globe Mining & Smelting Co. is opening a large deposit of ore that is to be mined by steam-shovel. The ore, a carbonate, occurs in sandstone formation. A 25-ton smelter is to be erected.

SALT LAKE CITY. The Edison Mica Mines Co. is to resume

work at its gold mine a little south of Little Cottonwood canyon.

WASHINGTON

CHEWELAH. On December 15 the United Copper Co. pays 1c. per share, equal to \$10,000. This is the first distribution for four years. The mine is in good condition. The mill is recovering 90% of the copper and 92% of the silver.

CLAYTON. The Silver Bell Mining Co., capitalized at 1,500,000 shares of \$1 each, of which 500,000 shares are to be held in the treasury, has been organized to take over and continue development of the old Spokane Belle mine, four miles from here. This is one of the oldest mineral locations in the northwest, and contains good silver ore. E. H. Belden, pioneer attorney, is president.

CANADA

BRITISH COLUMBIA

THREE FORKS. The Rambler-Cariboo Mining Co., with mines and a mill at Three Forks, has sold 1000 tons of concentrate stored at the property to the United States Zinc Co. for \$23 per ton. The product will average 34% zinc and 28 oz. silver per ton. Reports from the smelter have also been received stating that \$13,000 is due in settlement for lead-silver ore. Production of 1000 tons of zinc concentrate monthly is possible, in addition to the regular lead-silver output, according to A. F. McClaine, Jr., son of the president of the company, and it is probable that the entire zinc output will be taken by the United States Zinc Co., with the exception of a small amount for experimental purposes at the Anaconda Copper company's new electrolytic reduction works at Great Falls, Montana. Shipments of the 1000 tons of concentrate sold to the United States company will be made to its plant at Blende, Colorado, as soon as cars can be obtained.

ONTARIO

COBALT. During October the Nipissing mills treated ore yielding \$233,646. The refinery shipped 565,404 oz., including custom bullion. Underground developments were favorable. The most important were on four raises on vein 490 on No. 5 level. Here the average of each was 6 in. of ore assaying 1000 oz. per ton; some showed 10 in. of 1800-oz. ore. At shaft 81, 425-ft. level, a shoot was found in the Cobalt Lake fault-vein, 20 ft. long, 12 in. wide, assaying 1200 oz. per ton.

KOREA

The Seoul Mining Co., operating the Suan concession in Whanghai province, Chosen, reports a total recovery of \$138,250 for October.

MEXICO

The date when mines in the Republic shall become subject to forfeiture because of non-operation has been extended to January 14, 1917, in cases where conditions have prevented resumption of work. November 15 was the date set for the forfeiture of mines which had been idle for two months from September 14, the date on which the forfeiture decree went into effect. Luis Cabrera, chairman of the Mexican-American Commission, which is conferring at Atlantic City in an endeavor to settle outstanding differences between the two countries, notified the American commissioners on November 13 that General Carranza had extended the time-limit for the resumption of work in the Mexican mines for 60 days from November 14. He added that Mexico did not desire to confiscate property by trying to force owners to work it under impossible conditions, and intimated that the time-limit of the decree might be extended again, either for the entire country or for certain districts, should conditions warrant at the expiration of 60 days.

The San Francisco section of the A. I. M. E. will meet at the Engineers Club on December 12 to hear a paper on 'The Origin of Petroleum in California,' by John C. Merriam.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

FRANK MOSS is here from Western Australia.

CLARENCE J. PETERSON, recently at Tonopah, is in San Francisco.

ARTHUR WINSLOW was here, from Boston, during the past week.

E. B. KIMBALL has returned to San Francisco from the Wyoming oil-field.

F. G. COTTRELL lectured at Salt Lake City on November 20. He is now at Washington, D. C.

ARTHUR W. STEVENS is at Quartz, Tuolumne county, on the staff of the Dutch Sweeney mines.

F. M. FIELD of Virginia City, Montana, engineer for the Elling estate, has returned to Los Angeles.

C. T. HUTCHINSON, business manager for the M. & S. P., is at Denver, on his return from New York.

C. B. CLYNE is building a 100-ton copper flotation plant for the Werniger Mines Co. at Woody, California.

GEORGE F. ZOFFMAN, superintendent of the Cinco Minas mines, in Jalisco, Mexico, is here on a holiday.

ARTHUR JARMAN has resigned as assistant superintendent of the Grand Junction mine at Waihi, New Zealand.

F. R. WEEKES has been in British Columbia and California, and will return to New York the latter part of the month.

C. T. GRISWOLD, of the Associated Geological Engineers, is in Wyoming, and ERNEST MARQUAROT, of the same organization, is in Kansas.

C. E. MILLS, general manager of the Inspiration Consolidated, has been appointed managing director of the Cananea Consolidated in Sonora, Mexico.

P. N. NISSEN, the designer of the Nissen stamp, has added to his reputation by inventing a military hut, which has been adopted by the British army in France.

W. EARL GREENOUGH, for five years manager for the Marsh Mining Co., in the Coeur d'Alene region of Idaho, has resigned to engage in consulting practice. He has opened an office in the Old National Bank building at Spokane and will be assisted by S. B. DAVIS, formerly at Wallace, Idaho.

ARTHUR M. GREENFELL, formerly chairman of the Camp Bird, the Messina, and other mining companies, who became involved in an unpleasant and serious financial collapse just before the War, has distinguished himself in battle, having been promoted to Major and awarded the D.S.O. for conspicuous gallantry.

According to a Mexican refugee from Parral, Chihuahua, Mexico, who arrived at El Paso, Texas, on November 14, the Americans and other foreigners left Parral two days before General Luis Herrera evacuated the town. The Americans stated that before they left a party of foreigners in charge of LESLIE WEBB, an employee of the Alvarado Mining & Milling Co., was going to the town of Culiacan, near the west coast of Mexico, but the refugee thinks they are hiding in the mountains west of Parral, and gave out the story that they were going to the Pacific Coast to deceive the Villa bandits. The refugee said he knew that T. G. HAWKINS, JR., HOWARD GRAY, A. W. MORRIS, and BERNARD McDONALD had left Parral safely. Other Americans known to have been in Parral and believed by him to have left at the same time were: Dr. A. H. WHITLEY and son, Dr. T. J. FLANNAGAN, W. E. COWELL, W. C. PALMER, and JACOB MEYER.

WILLIAM RULE, managing director of the La Blanca y Anexas Co., died at Mexico City on November 5 at the early age of 48. His death is deeply mourned at Pachuca, where he had managed the mining interests of his distinguished father, Capt. Frank Rule.

THE METAL MARKET

METAL PRICES

San Francisco, November 24

Antimony, cents per pound	12.50
Electrolytic copper, cents per pound	31
Pig lead, cents per pound	7.25-8.50
Platinum, soft and hard metal, per ounce	195-111
Quicksilver, per flask of 75 lb.	\$80
Spelter, cents per pound	13
Tin, cents per pound	15
Zinc-dust, cents per pound	20

Platinum in London is \$18 per ounce, less than half the American price.

ORE PRICES

San Francisco, November 24

Antimony, 50% metal, per unit	\$1.25
Chrome, 40% and over, f.o.b. cars California, per ton	15.00
Magnetite, crude, per ton	8.00
Manganese, 50% (under 35% metal not desired)	16.00
Tungsten, 60% WO ₃ per unit	15.00

New York, November 15

Antimony. Little ore is to be obtained, as the price is considered too low to induce shipments from abroad. The quotation is unchanged at \$1.50 per unit.

Molybdenite. Offerings continue small, consequently trading has been light. The business done has been on the basis of \$1.75 per lb. for 99% MoS₂.

Tungsten. Business has been active, several hundred tons having changed hands for domestic consumption, leaving stocks low both at Pittsburgh and New York. Transactions are again recorded at \$17 per unit, at which figure contracts to cover the early part of 1917 have been made. Europe wants ore, but seems unwilling to pay the price. It is declared that Great Britain has contracted for the output of several South American mines over a long period. Japan, it is stated, is not permitting a free exportation of tungsten.

EASTERN METAL MARKET

(By wire from New York)

November 24. Copper is quieter though strong, first quarter being \$2.50; lead is stronger, independents advancing; the strong demand for spelter is unsatisfied.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	61.00	61.00	61.00

The position in silver appears to be strong, with an upward tendency. Supplies have been received at London with much regularity. India has come into the market, also China, though exchanges there remain steady, probably due to the reduction in metal stock at Shanghai, namely, 31,500,000 oz. since the beginning of the year.

Silver valued at \$630,000 was shipped from San Francisco to the Orient on November 11.

Tin is quoted at \$1.10 per lb.

The market for tin is quiet in New York, with quotations unchanged at 25¢ per lb., duty paid. Jobbers are getting 15¢.

ALUMINUM

No. 1 aluminum, 98 to 99% pure, is a little stronger at 61¢ to 66¢ per lb. on two lb. bids, jobbers are getting 75¢ per lb. The market is quiet.

Eastern Metal Market

New York, November 15.

The scarcity of copper for near-by and first-quarter deliveries, and the consequent startling advance in prices are finally narrowing activity. Not since 1873 have prices been at their present level—33c. for spot and 30 to 31c. for first quarter, having been paid. The enormous export sales, more of which are reported to be pending—all calling for future deliveries—have frightened consumers into paying almost any figure for metal they need. Brass mills and electrical companies have been big buyers. It is predicted that 35c. will soon be quoted.

A moderate, but steady business has been done in zinc, and prices have worked upward. No impairment of its strong position is looked for this winter.

Lead has continued quiet but strong.

In tin there have been some exceptionally active days in which brokers sought to cover their contract commitments. Great Britain is more strict in the matter of issuing licenses to ship. The New York price is higher.

Antimony is without feature.

Aluminum is 1c. higher.

The Pennsylvania Railroad has put an embargo on west-bound shipments originating at points east of Pittsburgh, also Philadelphia and other points. The New York, New Haven & Hartford Railroad is restricting shipments to points within its territory, and in each case the iron and steel and metal-working trades are sufferers.

Foundry pig iron is quoted at \$25 to \$26 per ton, furnace, on the Atlantic seaboard. For Southern iron \$20, furnace, is quoted.

Iron and steel pipe have been sharply advanced; black and galvanized sheets are higher.

Ship plates continue in enormous demand, and for forward delivery 4.50c., Pittsburgh, has been paid. For prompt plates, shipbuilders have paid 5.50c., Pittsburgh.

Much interest attaches to the 1917 prices to be announced for Lake Superior iron ore. It is believed that non-Bessemer ore will be \$1 higher, with a still larger advance likely for Bessemer.

COPPER

Sales of spot copper at 33c. are reported, and conservative members of the trade are predicting that the price will go to 35c. per lb. before the week is over. Prevailing prices are the highest since 1873. The enormous export buying, together with the great quantities contracted for by the large domestic consumers, has inspired a general rush to cover future requirements. As for those who are in immediate need of the metal they seem willing to pay any price. The situation is one which many term dangerous. Spot metal is extremely scarce, also that for first-quarter delivery, and there is none too much for the second quarter. Of course, one willing to pay the price can obtain any of these positions, but he has to look long and ardently for it. At the prevailing price an occasional consumer is willing to sell because of the attractive profit he can realize. Buying has been heavy for weeks, both on domestic and foreign account, but it was greatly stimulated by a report first heard November 11 stating that the French government was negotiating for 225,000,000 lb. for delivery in the second half of 1917. On November 6, the day prior to election, an enormous business was done. Since then the number of buyers has narrowed, but there still are interests which appear eager to buy any odd lots they can find. The market is somewhat difficult to quote for a specific delivery for the reason that sales are for varied positions. February electrolytic, on the 8th, sold at 20c. On the next day, prompt sold at 31c., first quarter at 30c., and second quarter at 29.50c. On the 10th, late November sold at 31c. On the 12th second quarter sold at 30c. early in the day,

and 30.50c. at the close. On the 14th, second quarter sold at 30.50c., and a sale of spot was reported at 33c., December at 32c., and January and February at 32.75c. It is a market where changes occur almost hourly. Lake is nominally quoted at the same levels as electrolytic. The London market for spot is higher, the quotation yesterday being £152, against £144 a week previous. Exports of the month are not large, amounting so far to only 7202 tons. Buying in the week just ended is estimated at upwards of 250,000,000 lb., including export and domestic business, not a small part of which was placed on the eve of election day, in fact, some of the producers declare November 6 to have been one of the largest days in their history. Makers of sheet copper have advanced their base to 40 cents.

ZINC

A steady, but moderate business continues to be done, with the brass mills the largest buyers, although exporters also are active. The galvanizers have been doing comparatively little in the market since the price left 10.50c. Two or three influences are giving great strength to zinc, one of which is an advance of \$10 in the price of ore at Joplin, making it \$90 per ton. A producer's representative figures that on this basis it costs about 10.50c., St. Louis, to make spelter. The cold weather has continued to interfere with the gas supply and consequently production, something that will be a factor through the winter. The price of zinc is expected to hold firm, barring slight ups and downs, until next March. Most of the business so far booked is for delivery to the end of the first quarter, although some deliveries in the second quarter are contracted for. Quotations in the past few days have worked upward steadily. The price for prompt yesterday was 11.50c., New York, and 11.25c., St. Louis; for December, 11.50c., St. Louis, and for first quarter, 11c., St. Louis. Exports continue on a large scale, those of the month, 1st to 15th, totaling 6396 tons. The London market for spot stood yesterday at £56, against £53 5s. a week previous. The makers of sheet zinc have advanced their base price to 17c., f.o.b. mill, carload lots, 8% off for cash.

LEAD

Not much can be said about lead. The market continues firm at unchanged prices. Both the leading interest and the independents are asking 7c., New York. At St. Louis the A. S. & R. Co. adheres to 6.92½c., but outsiders are asking 6.90c. Consumers are well covered. Much of the strength of the situation is due to the narrow margin between production and consumption. The London quotation for spot is unchanged at £30 10s. Exports to the 15th totaled 1022 tons.

TIN

Great Britain is chary about granting licenses to ship, and it appears that certain New York dealers and brokers have been caught with insufficient tin to cover their contract commitments. Several of these have been in the market in the past week and have bought large quantities. On the 11th and 13th these interests were active buyers, and on the latter day brokers and consumers bought at least 500 tons, leaving inquiry for several hundred tons unsatisfied. In the buying preference was given to tin aboard steamers that were actually named, inasmuch as this metal seemed more certain to arrive. On the 14th, probably 300 tons was dealt in, ordinarily a heavy day. The quotation for spot tin yesterday was 41.12½c., New York. Prices have been strengthened not only by the buying, but by the statistics which show that only 500 tons has arrived this month. Alloat is 4202 tons. The leading maker of tinplate has withdrawn its price of \$5.75 per base box and now asks \$6.

Industrial Notes

Information supplied by the manufacturers.

Liquid Rheostatic Control for Large Alternating-Current Wound-Rotor Motors

The extensive use of electric-motor drive for mine haulage, hoists, dredges, and similar applications brought to the fore the necessity for a controller for large wound-rotor induction-motors that would give wide and accurate speed variation, positive time-limit acceleration, and allow the motor to run at reduced speeds for long periods. To meet these conditions the Westinghouse Electric & Mfg. Co. of East Pittsburgh, Pa., designed the liquid type of control which is shown in the accompanying illustration. These controllers have been in successful operation in various applications for the last four years, and have proved equal to the most severe treatments.

A liquid controller consists essentially of a primary panel and a liquid rheostat. The former is made up of mechanically-interlocked magnetic-contactors for starting, stopping, and reversing the motor, oil circuit-breakers that entirely disconnect the motor from the line in event of an overload, a fused knife-switch for pump motor, and a low-voltage relay for the protection of operator and apparatus against voltage failure. The secondary control consists of a liquid rheostat complete

SECTION OF LIQUID RHEOSTATIC CONTROL.

with brass or wrought-iron cooling-coils for varying the resistance in the motor secondary, a pump and pump-motor switch for the circulation of the electrolyte, and a master switch for the control of the equipment. For plugging service a single lever *H* slot device and two overload relays are used. The two overload relays are mounted on the primary panel and protect the motor from overloads when running, but are short-circuited when plugging the motor. When operating under these conditions the circuit-breaker is set to protect the motor against exceptional overloads and short circuits on the motor, but too high to trip out in ordinary plugging service.

In the type of control shown, the depth of the liquid, in which the electrodes are immersed, is varied. This principle insures smooth acceleration and close-speed regulation of the motor, as an infinite number of steps can be obtained by gradually varying the depth of the liquid. It eliminates objectionable jerks and sudden strains in both the cable and equipment when starting loads of large inertia. The construction and operation of the control is so simple that even an inexperienced operator can obtain good results, and maintenance costs are low, since the electrodes are practically the only parts requiring renewal and these very infrequently. It is of especial value for heavy-duty reversing service, when starting is frequent and the motor is run at reduced speeds. It is furnished for any primary voltage and frequency and for either two or three-phase.

As shown by the diagram, the three secondary phases of the motor are connected to a set of electrodes suspended in the

electrode tank. The operating level is attached to an arm just above the master switch. When the lever is in the off position, the electrolyte, which is a solution of sodium carbonate (sal soda), is at its lowest level. When the operating lever is moved from the off position the contactors in the primary circuit are operated by the master switch and the weir raised. The electrolyte, which is circulated continuously by the pump, rises as the weir is raised. This immerses the electrodes more, decreases the resistance in the rotor circuit, and speeds up the motor. By adjusting the position of the weir the resistance in the rotor circuit is changed and the speed of the motor regulated.

A regulating valve in the pump discharge or intake pipe prevents the liquid from rising in the electrode tank at a rate greater than that for which the valve is adjusted. So the lever may be moved directly to the full-on position while the liquid will raise at the rate determined by the valve setting. The weir, however, is of such a size and design that the electrolyte will flow through the lower compartment speedily enough to take care of plugging when that is practised.

For plugging service the single lever *H* slot device and the two overload relays afford a positive protection against the wrong operation of the lever. To prevent over-travel in hoist work, either single or double-pole hatchway limit switches can be furnished. When the hoists are used for lowering, an over-speed device is desirable. Cam-limit switches form another means of protection, safeguarding against accident due to carelessness on the part of the operator. These consist of a number of switches operated by means of cams mounted on a hexagonal shaft connected to the driving motor or the driven mechanism through a chain and sprocket, or by a worm gear.

The Westinghouse company has sent us a little booklet entitled 'The Worker and the Works.' Photographs show exterior and interior views of the East Pittsburgh plant. Over 25,000 men are employed, receiving \$2,000,000 a month as wages. Sales are over \$1,000,000 monthly. Safety-first is a part of the welfare work for employees, which includes a magazine, club, night school, compensation and sickness funds, and pensions.

Commercial Paragraphs

The A. LUSCHEN & SONS ROPE CO., St. Louis, is now constructing an administration building costing \$100,000, adjoining its rope plant. The factory buildings of this company since 1903 have occupied a 33-acre site in the north-west part of St. Louis, while the offices have been in the down-town district. The new arrangement will result in increased efficiency.

William Cooper Cuntz, general manager and director of the GOLDSBURGH TRUNK CO., of New York, died on November 2, at Amherst, Massachusetts, where he was on a visit for the benefit of his health, which was impaired by an operation for appendicitis a year ago. He was born in New Jersey in 1871 of an old New England family. Mr. Cuntz was a member of 20 well-known societies and clubs in the East. His experience in the steel industry was extensive. He leaves a wife and two children.

A splendidly-arranged catalog, 9 by 12 in., has just been issued by the YUBA CONSTRUCTION CO. of Marysville and San Francisco, California. The frontispiece is a photo of the factory, and part of the globe showing that this firm's dredges are working in Alaska, California, Idaho, Montana, Oregon, Colombia, Siberia, and the Philippines. During the past three years Yuba dredges in California have dug 100,000,000 cu. yd. of gravel at a cost of 4.5c. per yard. The factory is in the centre of the dredging districts of this State. Special steel wearing parts have made Yuba dredges last a long time. Good photos show part of the shops, details of dredge parts, construction progress and launching of Yuba No. 15—the largest in the world—and boats in operation in many regions. Notes are given on the Yuba ball tractor, and cost of dredging.

EDITORIAL

T. A. RICKARD, Editor

OUR New York letter on the metal market will be found particularly interesting this week, especially in its references to copper.

CARRANZA'S government in Mexico has shown a better disposition lately toward American mining interests. The export tax on precious metals has been reduced and the threatened forfeiture of idle mines has been postponed.

SEATTLE has been selected by the Secretary of the Interior as the site for a mining experiment station to be operated under the direction of the Federal Bureau of Mines. Congress provided for three such stations, one of which was to be in the North-west. Tucson is to have the south-western station and Fairbanks will get the one intended for Alaska.

CYANIDE has risen recently so rapidly that the quotation now is 70 cents per pound, on new contracts; while on old contracts the price is a little less than half the figure mentioned. The chief manufacturer of this important chemical dislikes to enlarge his plant, believing that the existing market conditions cannot persist for long. The embargo on shipments from Europe has curtailed the imports of cyanide, so that the American supply is wholly inadequate.

LEAD mining in Missouri is the subject of an article by Mr. Sydney H. Ball. It is the kind of article that the editor is glad to receive and to publish, for it is written with a care and a skill that render even a dry technical subject easily assimilable by the enquiring reader. The ore deposits of Washington county, Missouri, are among the more interesting of the concentrations of metal that furnish scope for small-scale operations, and the economic geology of them has a scientific interest quite as great as that of the bigger accretions of ore in other regions.

FIRST AID to the injured in and about mines, is one of the most important of the many humanitarian innovations of recent years. Friendly contests between rival first-aid teams of important mines have come to be a feature at official gatherings of mining engineers and others engaged in the mining industry. These contests have a direct tendency to promote efficiency and speed in the rendering of aid to the injured, and are a decided relief from the traditional prize rock-drilling contests that have so long been popular. Whether these latter

trials of skill were of any real value is extremely doubtful. Rarely, if ever, was the man who won the prize as the champion driller on county-fair day the best miner, nor was he ever known to so far forget himself as to give any demonstration of his skill except when drilling for a prize.

AN editor discovers that he has critical readers as soon as he permits a blunder to appear. In a recent issue we spoke of the gold in the world available for monetary purposes as worth eight billion dollars and stated that this was equivalent to the amount of gold in a cube of 60 feet. This is incorrect. Taking the density of gold at 19.32 and a cubic foot of water at 62.42 pounds, we find that one cubic foot of pure gold weighs 1465.569 pounds Troy. This, at \$20.67 per ounce, equals \$363,519.734. Dividing 8,000,000,000 by this figure, we get 22,007.058 cubic feet, or a solid cube of pure gold measuring 28.023 feet on each face.

DISCUSSION this week starts with a most timely letter on 'Electrolytic Practice' by Mr. S. E. Bretherton, a metallurgist of much experience. He gives some useful hints to the Western mine-owner and dwells upon the better market offered to the purer product of the electrolytic refinery, particularly that of zinc. On this branch of the subject he has more to say, reciting some of his own experience at the Afterthought mine in California. Mr. William Hague, managing director of the North Star Mines, testifies to the usefulness of the summer training-camp and endorses the plea made by Mr. A. H. Babcock in our issue of the 18th inst. Mr. T. Nipper writes from board ship, but in his remarks he is not much 'at sea.'

TALES of fabulous deposits of native copper have been brought to San Francisco by Capt. C. T. Petersen, of the Stefansson expedition. The explorers found the Eskimo sewing their clothes with needles made of copper. This was on Banks island, which is about 550 miles due north of Great Bear lake. This story recalls the finding of native copper in the Coppermine River country by Samuel Hearne in 1770, by others since, and finally the expedition of Mr. George M. Douglas, who, in 1911 and 1912, penetrated into this remote region and made a careful investigation, as related in his delightful book 'Lands Forlorn.' He and his friend, Dr. August Sandberg, a Swedish geologist, found copper in the amygdaloidal portion of basaltic flows and in beds of conglomerate, resembling those of the Lake Superior country. No rich ore was discovered, but the samples

brought home suggested possibilities of large-scale exploitation in days to come. Similar copper finds have been made on Bathurst inlet, on the west side of Hudson's bay, 500 miles to the east. Evidence accumulates to indicate a wide distribution of copper in the Arctic regions of this continent, and we do not doubt that some day a thorough exploration will be made in search of orebodies rich enough to warrant mining on a large scale. Among those that are making millions out of the current inflation of copper shares there should be two or three willing to find the money required to equip an expedition to explore the territory between Hudson's Bay, the Coppermine river, and Banks island.

COST of living is a phrase that covers a multitude of extravagance. The present rise is due largely to our way of living, which has been in no way modified by the exigencies of an industrial crisis. "Wilful waste makes woeful want" is an old proverb that applies to this country today when the rate of personal expenditure knows no check and the exhaustion of natural resources to take advantage of abnormal markets is being hastened apace. While prices of staples rise there is yet no sign of a diminution in the buying. New York is given over to an orgy of dissipation and the new millionaires are spending money like drunken sailors. Half the world is in mourning and the other half is indulging itself in riotous luxury. Is this our notion of 'preparedness' for the crisis that must come after the War as surely as there was one when the War began? It behooves us to be serious in times like these.

MAJOR-GENERAL GOETHALS, Governor of the Panama Canal Zone, has replied to sundry criticisms and predictions unfavorable to the great work for which he is sponsor. In his annual report, now made public by the War Department, he complains that some of these criticisms have affected the commercial rating of the Canal and tended to diminish traffic. This traffic is small enough to need some apology, for the average of a ship per day each way is far below all reasonable expectations. Only 91 vessels engaged in the American coastwise trade used the Canal during twelve months. General Goethals asserts that there is much ignorance on the subject of slides. There may be, but criticism of the Canal engineering is not confined to those that are ignorant. For instance, nobody in California supposed that slides affect the entire length of the cut, but it is worthy of note that the portion of the Canal thus affected is slightly less than one mile. However, a mile of ground, if it starts to move, is an engineering obstacle of the first rank. General Goethals has no patience with the report of the commission sent to Panama by the President in October last year and he protests against a report by the professor of geology in Lehigh University, Mr. Benjamin Le Roy Miller. His main objection is based on the fact that Professor Miller spent only "three or four hours" in his examination, but that may have sufficed to give him the data necessary for an opinion. The objection smacks too

much of the criticism of adverse reports on a mine because a competent engineer did not spend as much time on it as a stupid man might find necessary before he could formulate an opinion. The quotation from Professor Miller's report is much like the description given by Dr. John C. Branner, for whose opinion the mining profession has a high respect. As to ex-Senator Thomas Kearns and his theory, it surprises us that General Goethals should pay so much attention to it, unless it be that the theory put forward by the ex-Senator gives the General a chance to ride off the field with a flourish. We find nothing in the extracts from General Goethals' report, as published in the daily press, to allay our anxiety concerning the safety of the Canal or to encourage the expectation that the slides can be stopped at an early date.

SEVERAL daily newspapers have doubled their price and a number of magazines have been compelled to increase their rates of subscription on account of the higher cost of paper. Most of this is the result, not of a scarcity of wood-pulp, bleach, and other materials used in the manufacture of paper, but of a cinch—in plain words, of a combination between the manufacturers to raise prices, on the excuse that they expect to be compelled to pay more for their crude material. The allegation that such a conspiracy does exist has been made by the American Newspaper Publishers Association, and it is to be probed by the Federal Trade Commission on December 12. The declaration of huge dividends by the paper manufacturers is fairly good evidence that they are not suffering from any shortage. The press ought to be able to protect itself against imposition. We feel confident that it will be disclosed that the paper market, like many others, is being manipulated under cover of the so-called effects of war; like the man who raised the price of eggs and imputed the blame to "the War." On being pressed for an explanation, he stated that he had to send the shells to Europe! "War is shell." Many of the greedy gentlemen that are taking advantage of our necessities at this time have no better reason for their extortionate demands.

ORDERS have recently been received at the local office of the Federal Bureau of Mines to the effect that the San Francisco office, in the Custom House building, will be no longer a distributing-point for the publications of the Bureau. Only such publications as happen to be on hand at the date of this order are to be delivered to those making application for them. Also the chemical laboratory that for several years has been maintained in the Appraiser's Building, in San Francisco, has been discontinued. The latter may possibly be spared without working a hardship on any one in particular, as chemical analyses and experiments can perhaps be made to better advantage at one of the larger and more fully equipped experiment-stations, but it seems unfortunate that the public on this side of the continent should be compelled to write to the main

office of the Bureau of Mines at Washington for any of its publications that may be wanted. The U. S. Geological Survey maintains an office in the Custom House building and we see no reason why that distributing agency should not be utilized by the Bureau of Mines as well. It is high time to save some of the public money that is wasted by the scattering of administrative energy. Both bureaus are in the Department of the Interior. We hope that the Secretary, Mr. Franklin K. Lane, will be made aware of the facts and act in the matter with his usual good sense.

Copper 'Investments'

In our last issue we published a letter from Mr. Ira B. Joralemon on the efforts being made to gull the public with iridescent copper prospects. Since then we have received a good example of the sort of propaganda used by the peddlers of shares in wild-cats. In the Albuquerque Journal we find a prospectus that offers stock in "a company in the right location, namely, about three miles north of the United Verde and one mile west of the Santa Fe railway." The second fact is more significant than the first; three miles is far enough from a celebrated mine to thin out the orebodies to a *hilo*, while a mile from a railroad is what is usually called in a prospectus "facilities for transportation." The inevitably "well-known engineer," whose name we forbear to mention, states that the surface of the property shows "lime and chert flows," suggesting an unusually high temperature at the time of eruption, for chert contains a good deal of silica, we believe. This is bad enough, but the Albuquerque type-setter breechates the text of the "well-known engineer," so that he is made to state that the "underlying"—that's a good word—formation is "shist and diorits" in which "quartz and calceide matrix" are on the rampage. Indeed it is the delirious trimmings of geology and must have caused a rush for the "pre-organization stock" offered at 10 cents per share—going fast—"buy it now, before it is too late." As a final argument the simple-minded "investor" is told that "it is on the same fault with the United Verde and the United Verde Extension." Perhaps it is. Mr. J. P. Morgan lives in the same street as a pea-nut vendor; it may be at the other end; and real-estate values fade out at that end; but still it is in the same street. "The same fault," yes, the same as that of some high-class share-brokers in New York that are circularizing suggestions about copper shares as an 'investment.' Such a suggestion is as arrant a bit of humbug as that of the disseminated wild-cats. Nobody who buys copper shares when the metal is selling at 33 cents is participating in an 'investment.' Buyers of such shares expect to sell soon at a profit, leaving the other fellow to 'hold the bag.' Plainly, it is a gamble. Even if a mine can pay reasonably on 15-cent copper, a sane man does not buy the shares when copper is more than twice as high, for the simple reason that he can obtain his 'investment' at

much nearer an investment price when the market breaks, as break it must when the big rush for copper is abated. On the whole, the wild-cat incubator has more of our respect than the experienced financier in his marble-decked offices in the New York sky-scraper that talks to the public in dignified phrases at this time concerning the "investment worth of copper shares." That is bunco-steering and nothing else.

The Bureau of Mines

We take pleasure in publishing the larger part of an address delivered before the American Mining Congress by Mr. Van. H. Manning, the Director of the U. S. Bureau of Mines, on the subject of 'Federal Aid to Mining Efficiency.' It was eminently proper that Mr. Manning should avail himself of the opportunity to inform the public on such an important matter and that he should select the Congress as his medium of transmittal. This is the most valuable function that the Mining Congress can perform; it is a convention of those interested in mining as a national industry; at its annual meeting all the various elements contributory to the welfare, efficiency, and expansion of mining are represented, without distinction of class or profession. The technical societies serve their particular purpose and chambers of commerce have their own usefulness, but it is fit and proper that once a year the representatives of the mining public should assemble to make known the wants, legislative and industrial, of the great business to which their energies are devoted. We are informed that the recent meeting at Chicago fulfilled this purpose and that the proceedings were full of interest, particularly to those engaged in coal mining, which, naturally, absorbed the larger share of attention at this particular meeting. Mr. Manning's address should be read by every good citizen engaged in mining. The comparison between the financial aid given to the two basic industries is one that is often made and the latest figures emphasize the curious discrepancy in the allotment of Federal support. Undoubtedly one reason, not mentioned by Mr. Manning, why the miner obtains less help than the farmer is the general supposition that mining is more speculative than agriculture and that those engaged in mining make money more freely than those occupied in tilling the soil. The mining 'game' is one that the average legislator usually regards as bringing its own gains and losses through methods that do not call for special endowment. This misconception is fostered by the spectacular side of speculation in mining shares. Miners readily turn their property into stock companies whereas farmers rarely seek to distribute their risk in a similar way. Nevertheless, the relation of the mining industry to the State is becoming better understood, particularly the many forms of mining that do not lend themselves to stock speculation and represent something akin to what is called an 'investment.' However, even the uncertainties and risks incidental to most forms of

metal mining should not debar a full measure of Federal aid and support, for similar vagaries of fortune characterize other national industries, such as fishing, that receive adequate assistance. With the competition for appropriations between the various branches of the Government the citizen need not sympathize; the mere fact that one department gets a larger helping from the pork-barrel than the other is not a valid grievance, until it is proved that the larger appropriation is ill spent. It is a great pity that financial support should be dependent upon annual lobbying at Washington. Under ideal conditions it should be as unnecessary as it is undesirable for members of a scientific service to have to curry favor with legislators in order to obtain the votes of money required for the proper performance of their work. Sometimes one is tempted to wish that a direct tax, say, of only 4%, could be levied on our mineral production for the maintenance of the scientific bureaus and that the income thus obtained could be divided in equal proportions, so as to end the annual scramble. One matter that requires attention is the persistent duplication of work, particularly the double collection of statistical information by the two Federal bureaus and by the various State bureaus. Another is the lavish printing and distribution of stuff that has little value. It has become too easy to print inconsequential collections of data for the purpose of swelling the apparent output of a bureau and for the personal gratification of minor officials. We receive a good deal of printed matter from Washington that goes into the waste-paper basket with a celerity more eloquent than any criticism. If any commercial publishing-house were to distribute its output in the same reckless fashion, it would soon go into liquidation. Much of the lavish distribution of papers, circulars, and statistical compilations is intended to impress the uncritical public with the activity of the particular bureau or service from which it emanates. The consequence of most importance is the wasting of good money that is needed for other and much more useful purposes. These suggestions must not be taken as indicating any general criticism of the good work being done by the Bureau of Mines. Our readers are well aware of the successful development of the 'safety' campaign and the consequent saving of human life in the mines of the country. Investigations into the hygiene of mining have proved highly effective in promoting the health of the workers. In technology, much has been done to stimulate the profitable exploitation of the secondary minerals and a number of technical investigations have been brought to the point of fruition, yielding information already adopted in current operations. From this assistance the mining industry will benefit, but we confess that we are jealous of an invasion of the field of engineering practice and hope that keen discrimination will be shown in the selection of subjects for experimentation and study so that individual initiative will not be subjected to unfair competition. We would like to see the development of a policy whereby the individual technician could get assistance, rather

than competition, from these Federal bureaus. In this and kindred matters we look to Mr. Manning, who follows so worthily in the footsteps of Holmes, to steer between violent extremes. The U. S. Bureau of Mines has won public support and will, we feel assured, continue to deserve that support.

Mergers

The New York financial press contains references to 'merger rumors' or schemes proposed for consolidating various mining companies, chiefly those exploiting copper. The Utah, Braden, Kennecott, Chile, Cerro de Pasco, Inspiration, and Nevada Consolidated are among those mentioned. However "nothing definite has yet developed," we are told, because among other deterrents is the suggestion that the Federal government might consider such a consolidation as conflicting with the anti-trust laws. The group of mines mentioned is producing half the copper of the United States or half of what was the world's production before the War. Another 'merger,' said to be under consideration, is a consolidation of the Alaska Gold and the Alaska Juneau. For this rumor there is no reason, we believe, except the wish to obscure the disappointment of the promoters, more particularly the brokers, behind the Alaska Gold enterprise. It is extremely unlikely that the controllers of the Alaska Juneau will entertain the idea. A little consolidation, like Scotch and soda, is an excellent tonic, but we have seen the idea stultified in South Africa and in other regions during the last decade. The recent agglomeration called the Kennecott Corporation has no excuse except the facility that it afforded for a little financial ledger-remain. Most of the big consolidations on the Rand served to disguise the union of poor mines or disappointing properties with the richer producers, thereby enabling the 'big houses' to rid themselves of junk. Moreover, the confident predictions of a lower working-cost, to follow such consolidations, have proved fallacious. There is an economic limit to the size of any unit, whether it be a mine or a mill. There is also a limit to human capacity. By merging mines one after another and creating a huge complex of operations, a point is reached where no engineer, however competent, can exercise anything like close supervision. His duties have to be deputized to extinction, so that the administration becomes unwieldy and inefficient. In short, super-mines are easier to make than super-men. To join the Utah Copper to the Chuquibambata will produce no economy; both are quite big enough to tax the executive ability and the technical supervision of any man. One being in Utah and the other in Chile, the object of consolidation is not obvious outside a stock-broker's office. If the idea is to give a broader basis to the operations and a greater stability to the output, then we reply that the consolidating of all the copper mines in the world—unless accompanied by an arbitrary monopoly of the market—would not eradicate the one factor that renders copper mining speculative, namely, the price of copper.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Electrolytic Practice

The Editor:

Sir—After all these years of 'watchful waiting' on the part of the owners of Western mines containing complex ore, called by the smelter men 'refractory' ore, we now have brighter prospects for the future. 'Complex ore' is an ore containing metals that interfere with the recovery of other metals of value, more particularly zinc in a sulphide ore containing gold, silver, and either copper or lead, and sometimes all of these metals in the same ore in addition to considerable zinc. If the proportion of zinc is under 40%, the ore cannot be classed as a zinc ore, and if it could the zinc smelter does not want the other valuable metals. The zinc increases the cost of recovering the other metals, no matter who does the smelting, so that the usual penalty charged over 10% by the smelters, 50 cents per unit above 10% (a unit is 1%) added to the charge for treatment is to be expected. Now, if the penalty on an ore containing, say, 20% zinc equals \$5 added to the value of 400 pounds of zinc lost (360 pounds should be recovered at a value of 5 cents per pound at least); the owner is out \$23 per ton on account of poor metallurgical practice. I feel confident that we are now about to experience a change for the better. First, the large mine-owners who are strong enough to do so and have the mining property to justify, are now installing expensive leaching-plants to recover and market all five metals from the same ore, such as gold, silver, copper, zinc, and lead. The next step will be for these same reduction plants to purchase custom ore and pay for the zinc with the other metals and, instead of penalizing it when over 10%, pay for it. If they fail to do so, some enterprising capitalist will start an independent reduction plant to purchase complex zinc ore, the same as the lead and copper custom smelters are now doing for their ore.

There is one view of the situation that perhaps most zinc-mine owners, who have no reduction plant of their own, have lost sight of, that is, we cannot expect the owners of a mine owning their own complete reduction plant to purchase custom ore while the prices of metals are abnormally high, if they can supply their reduction plant with ore from their own property. When metal prices are low is the time to conserve their own ore-supply and purchase ore from others and at the same time avoid the risk of buying on a high market and selling on a low market. It requires several weeks or months to treat the ore and get the metals sold in the East.

I started to write an article of encouragement to the

Western owner of complex ore but so far I have written on discouraging lines. Now I wish to show how the Western mine-owner of the so-called complex ores (in the past practically worthless on account of their being so difficult to treat) is going to have the advantage over the zinc producers in the Eastern states: The inland zinc-producing States are no closer, from the standpoint of freight-cost, to the New York market; in fact, not as close as San Francisco is with cheap water-transport, now that the Panama Canal is completed.

The West Coast states have much more available water-power for generating the cheap electric current necessary for the production of electrolytic zinc. This electrolytic zinc, on account of its purity, will in time, I believe, drive most of the retort zinc from the market, and others more capable of judging take the same view of the situation. Objection will be made to this statement on the claim that the less pure retort spelter of the East answers the purpose for manufacturing most of the alloys into which zinc enters, but the manufacturers of brass and of paints prefer the pure article; in the one case pure spelter and in the other pure zinc oxide, so that they can always use the same definite proportion of zinc in their alloys and zinc oxide in their paints.

The much despised complex zinc ores of the West will also have the advantage over the Eastern zinc ore in having other metals to share the burden of expense, often enough of these to defray all the expenses of mining, treatment, and marketing. Before closing my remarks on the future advantages that the Western zinc-producers will have over the East, I must add a little boost for the Pacific Coast states, especially California, by calling attention to our favorable climate the year round, without such extreme heat in the summer or such extreme cold in the winter as interferes with the efficiency of labor.

I think it unnecessary to call attention to the troubles the Eastern zinc-smelters are having in the failure of the natural-gas supply for fuel, compelling them to revert to the more expensive coal-fuel. While some of the Eastern smelters claim to pay for the copper, silver, and gold contained in a zinc ore or concentrate, their metallurgical loss is so great that after paying a low rate for the zinc, they offer to pay only for a little more than half of the gold, silver, and copper contents. If they pay for any of these last-named metals, an additional charge is made for treatment. It is not right to condemn these people for such practices, considering the antiquated methods of treatment they are using and compelled to continue to use by force of circumstances.

The Eastern zinc-producer has had one great advantage over the West in the past, before modern leaching methods were commercialized to treat the zinc ore containing other valuable metals: throughout the Mississippi Valley states the ore, although low-grade, is comparatively near the surface. It contains either lead or zinc, easily separated by concentration into clean high-grade concentrate, close to the zinc smelters in the coal-fields, and lower freight-rates to New York, where the spelter is sold.

This difference in freight-charges has been equalized by water-transport through the Panama Canal. The new leaching processes for treating zinc ore do not require the cheap fuel, necessary as a reducing agent, used in the old Belgian retort method, and for power purposes California has cheap fuel-oil in addition to water-power.

No one man or company is entitled to the credit of the wonderful advancement in zinc metallurgy made within the last few years. Several metallurgical chemists have experimented, but most of them lacked the financial backing necessary to prove whether their ideas were right or wrong. Improved methods of concentration, more especially flotation, which eliminates the old fear of making too much slime and also increases the recovery of the metals from the ore in a concentrate, has assisted the beneficiation of all metals. This high recovery of the metals in a concentrate, at a very low cost per ton of ore, not only eliminates most of the minerals that interfere with either retort-smelting for zinc or the leaching process, but also reduces the tonnage necessary for final treatment by the more expensive methods.

The idea of leaching zinc from an oxidized ore or an ore oxidized by roasting appealed to most of us from the start, but we soon learned the danger of forming insoluble combinations with the zinc if the roast was carried at too high a temperature. When roasting zinc ore the temperature must be higher than is necessary for the roasting of either copper or iron ore. Then, after the zinc was in solution, the most serious difficulties were encountered, that is, not only to obtain a pure zinc but also a solid zinc cathode suitable for melting into marketable bars. The problem of precipitating a solid zinc cathode was solved if an absolutely pure zinc precipitate could be obtained, the last traces of iron being one of the most difficult impurities to eliminate. The experience of F. L. Wilson at the Afterthought mine when experimenting with the ammonia carbon-dioxide process was the same, for although our solvent was not supposed to dissolve any of the iron with the zinc and copper, traces would nearly always finally get into the resultant zinc oxide, just enough to make it a little off-color. My own three years' experience as chemist at custom lead smelters when a boy made me appreciate the difficulty of precipitating the iron from an alkaline solution unless it had been previously oxidized from the ferrous state to the ferric, as we made a practice of doing with an oxidizing acid or salt in the laboratory before precipitating the iron with the arsenic, if there was any present. But these expensive chemicals could not be used on a com-

mmercial scale. It was on account of so many more impurities getting into the solution with an acid solvent than with an alkaline solvent that I favored the ammonia carbon-dioxide process, and even then we found traces of iron would finally show up in the zinc oxide.

Frederick Laist, chief metallurgical chemist with Frederick F. Frick for the Anaconda Copper Co., found that manganese ore answered the purpose and patented their ideas in U. S. patents No. 1,167,700 and 1,167,701, issued on January 11, 1916. With the enterprising policy and strong backing of such people as the Anaconda company, combined with their own ability, they finally developed their present zinc-leaching plant on a large scale.

While the Anaconda company was improving its process, the Bully Hill Copper Co. was developing a little different acid-leaching process briefly described in two U. S. patents (No. 1,154,601 and 1,154,602) issued to Otto Best on September 28, 1915. The idea of using manganese dioxide to oxidize the ferrous iron to a ferric iron had been adopted by Alexander T. Elliott of Los Angeles in 1908, as described in his petition to the Commissioner of Patents on September 5, 1908. What he claimed was that ferric salts would dissolve copper and zinc from an oxidized ore, reducing the ferric salts to the ferrous state, and that he re-generated ferrous salts back to ferric by the use of MnO_2 . I spent a few days at that time investigating this process, but was not satisfied with the extraction obtained or the quality of any zinc product we could get from the solution.

Several years ago I was requested to investigate a process in Oakland to recover the zinc with all valuable metals from the Afterthought ore. I was told by the old gentleman who had the process that he used no acid and that his chemicals cost nothing; all that he used was water after a long-time roast. He would neither let me have any of the residue nor explain anything that he used. As he made a mystery of the process, would not let me have any of the residue, and stated that he would not patent his process, I lost faith in the scheme. Had he given me any of the residue, and had we found it to contain some manganese, I doubt if even then I should have suspected that it had been added to the original ore before roasting. It was only recently that a friend of mine who had to investigate some of the work Charles Best had been doing before he died, learned that his secret was the addition of manganese ore to the sulphides before roasting, which helped to oxidize the sulphur, forming a complete reaction to sulphates of zinc and copper, so that after roasting the addition of water would leach out as much as 95% of the zinc and copper from such ore as the Bully Hill or Afterthought mines.

San Francisco, October 25,

S. E. BRETHERTON.

[We thank Mr. Bretherton for his interesting contribution and hope that other metallurgists will feel prompted to discuss the subject. This phase of metallurgy is of the greatest importance in the West where electric energy can be generated cheaply, and where coal is so expensive.—EDITOR.]

Officers Reserve Corps

The Editor:

Sir—I have read the article on 'Engineers for the Officers Reserve Corps,' by A. H. Babcock, appearing in your issue of November 18. Permit me to add a mite to the exhortation at the end of the article. As one of ten or twelve thousand who put in a month at Plattsburg this summer, I have a better conception now of the highly technical training required of an army officer; of the inadequacy of one month's training to make a 'rookie' competent to fill any military position; and of the fearful condition that would result if this nation should become involved in war while it has an insufficient supply of officers and relies on untrained volunteers to make an army. Inheritance of the rights of citizenship in this nation obligates all of us to service. One's feeling of generosity in giving a month's vacation to the country, in undergoing training, soon changes, after contact with Army officers, to the realization that an overdue debt to the nation is being paid in part. Therefore, engineers who can possibly spare the time, should at least allow the Army officers to 'take a crack' at them, so that if they are wanted they may have some military training when called upon. The two weeks' training—and it should be four weeks—demanded each year, for five years, of officers in the Reserve Corps, if it is anything like Plattsburg, will prove a most interesting and a valuable experience; the benefit of the physical training alone being worth all the trouble involved. A regular Army officer makes a very spry citizen out of even a fat man. Engineers should "do their bit" while the going is good.

WILLIAM HAGUE.

Grass Valley, November 19.

[This testimony to the value of the summer training-camp is timely; so is the hint of the duty owed by the citizen to the State, especially by the more intelligent type of citizen, such as the engineer. We hope all of our readers have read Mr. Babcock's article, and that having read it they will appreciate the propriety and privilege of doing their share of service to their country.—EDITOR.]

Regarding Foreign Capital

The Editor:

Sir—The way to obtain the greatest possible utility from foreign capital is to do as the keen legislators in one South American republic are planning to do. Begin by simplifying the regulations regarding the location of mines and their purchase. Allow the foreigner or the foreign company to operate under favorable conditions. In this way, properties that are of absolutely no value to the present owners, on account of the money required to develop them, can be sold to foreigners, who will invest money, employ labor, buy produce, pay freights and duties, and ship copper and iron ore.

When there are enough large companies operating and sufficient jealousy among the citizens of the country, it is a simple matter to put an export duty on all shipments

of minerals or metals exceeding a fixed tonnage. This tonnage will be chosen so that all native companies escape the tax and all foreign companies pay the tax. After the foreigners are once in, they cannot get out, and an income running into the millions can thus be obtained. Of course care must be taken not to take all the profits, or if these are taken, it must be only in cases where the foreigner has hopes of increasing his profits to a point where they will exceed the tax.

There are some statesmen that think, with your correspondent Mr. M. B. Yung, that mines should not be sold to foreigners. This is the condition in Paraguay—and look at the result! With such premises, assume that all of us Westerners decided that too many Easterners were making money in our Western mines, and therefore decided that no one from east of the Mississippi might own mines in our Western States. That would be so fine that those of us in California would carry the plan a step further and decide that only Californians may own mines in California. This would work so well that San Diego county would pass a law allowing only natives of San Diego to own mines in the county. This would help the county so much that the Julian district would copy, and only Julianites might work mines in Julian. Now, as the people in Julian are in exactly the same position that the Chinese and the South Americans are (no money to work their mines) it should be quite clear how rapidly the mineral industry is going to develop in China under Mr. Yung's scheme.

Mining is not exactly what the outsider considers it. The expression 'mining company' is not exactly synonymous with 'good business' though many 'statesmen' seem to think it is (including statesmen in the United States). No, it isn't all profit, as many an investor has learned, to his sorrow.

Once there was a very little boy who had heard his father and mother discussing "putting money into the mine" and the money they would take out of it. Upon his first visit to the property, he had no hesitation in going down the narrow twisted workings, always seeming to be looking for something. When they came to the surface, father said, "Well, son, what do you think of the mine?"

"I didn't think a mine was like that!" he said, hesitatingly.

"What did you think it was like?"

"Why," he said, after some study, "I thought it was a great big machine with two holes in it. One hole to put in a little money and the other hole to take out a lot!"

At Sea, November 5.

T. NIPPER.

THE zinc output of New South Wales has increased greatly the past 10 years. The British government has agreed to take 100,000 tons annually of zinc concentrate from that province during the War and for 10 years thereafter, and also to take 45,000 tons of spelter made in Australia. This will require about 115,000 tons more of zinc concentrate.

Federal Aid to Mining Efficiency

By Van. H. Manning

INTRODUCTION. *On two foundation industries, agriculture and mining, the welfare and prosperity of this country rest. Agriculture is unquestionably still the greatest of our industries, but mining is easily second in importance. The value of the products and the number of men employed by these two industries are sufficient evidence of this fact.

In this country agriculture received aid from the Federal government and the States long before mining, and today, as far as official encouragement is concerned, agriculture is the best organized of all our industries. You will find agricultural organizations in every State in the Union; in addition, there are several great national organizations, any one of which is at all times ready to call attention to the needs of agriculture.

Mining is becoming better organized and a number of organizations, notably the American Mining Congress, are now working in its behalf, but we have much farther to go to reach the stage of organization attained by agriculture. This organization of agriculture is reflected by the activities of the Federal government. With the Department of Agriculture back of this industry and several thousand skilled men looking after its every interest; with Congress for many years educated to the needs of agriculture, it is a comparatively easy matter for agriculture to get what it wants in the way of appropriations.

I have had some comparative statistics prepared concerning the two great industries and some of the conclusions reached are almost startling. According to these statistics, mining is not receiving from the Federal government anything like its just share of the appropriations annually made. The statistics show that if mining were to receive the same consideration as agriculture, comparing the relative value of the outputs of the two industries, mining would receive nearly four times as much as it now receives, or \$8,018,560 instead of \$2,333,075. Another interesting comparison shows that the Federal government in the present year has donated to the farmers one dollar for every \$295 worth of products of the farms. It has donated to mining one dollar for every \$1047 worth of products from the mines.

I am pleased to say, however, that mining is beginning to receive more recognition. Last year Congress passed a law providing for the establishment in several important mining regions of the United States of ten mining-experiment stations and seven mine-safety stations in addition to those already established, but providing that not more than three of the mining-experiment stations

and the same number of safety stations shall be established in one year.

Having thus called attention to the comparative financial aid given by the Federal government to the two great industries, I shall summarize somewhat briefly the work done by the Department of the Interior in its efforts to aid mining. That Department, as you know, includes the two Federal bureaus, the Geological Survey and the Bureau of Mines, whose activities relate almost wholly to the mineral industries.

No other country in the world has such vast and varied mineral resources as the United States. In 1880 the value of the mineral products of this country, according to the Tenth Census, was \$364,000,000; in 1900 the value had risen to \$1,063,600,000; in 1910 to \$1,991,200,000; and in 1915, according to the advance figures of the Geological Survey, to \$2,373,000,000. From 1880 to 1915 the population of the United States increased about 100%, whereas the value of its mineral production increased nearly seven-fold.

But this tremendous increase in production has been accompanied by unparalleled waste, in both the production and utilization of our mineral wealth, with too little regard for the health and safety of the men whose labor converted the natural resources into the commercial products. A people of restless energy, individualistic, eager for immediate success, and having little regard for the lessons of the past, we have indulged in an orgy of hasty exploitation, with the result that already we are nearing the limit of maximum production of some minerals, although the original supply, if wisely mined and utilized, would have lasted us many years longer and would have brought us ten times the wealth. To conserve our remaining supplies, that is, to extract, prepare, and utilize the minerals and ores in such manner as will be of most benefit to the Nation, is not a simple nor an easy task. Our mineral resources are many and extend throughout great areas, occur under widely varying geological conditions, and are subject in large part to State laws that differ greatly.

Evidently no one State should be expected to bear the cost of investigations that are of interest to all the States, and for each State to undertake such investigation would cause much duplication of effort and unnecessary expense.

THE BUREAU OF MINES. Investigations of the causes of mine explosions and the methods of preventing such explosions were begun by the Government in response to a general demand that measures be taken to lessen the loss of life in mining operations. When it established the Bureau of Mines, Congress directed the Bureau to investigate not only mine explosions, but also mine acci-

*An address delivered by the Director of the Bureau of Mines before the American Mining Congress at Chicago on November 15.

dents in general, and the conditions that affect health and safety, and also to investigate methods of mining, treating, and utilizing mineral substances with a view to economic development and the prevention of waste.

For purposes of administration, the investigations conducted by the Bureau are grouped in five divisions: mining, fuels and mechanical equipment, mineral technology, metallurgy, and petroleum, each in charge of a chief engineer.

SAFETY INVESTIGATIONS. The early activities of the Bureau centred about investigations to determine the causes of explosions in coal mines, the methods by which such explosions could be prevented or checked, and the development of safer and more healthful conditions. Consequently, the most notable result of the Bureau's efforts during the past six years has been the arousing of a wider interest in greater safety and more healthful conditions in mines and metallurgical plants, and the gaining of the co-operation and active aid of all possible agencies in the progress of improvement.

The Bureau of Mines makes no claim to having been the first agency to call attention to the high death-rate among miners; nor does it claim it was the first to urge the need of safer methods. It has gladly welcomed the aid of all agencies that have sought to better conditions, and it freely concedes the credit that is due them for what they have done. The Bureau does claim, however, that its work has served to stimulate a nation-wide movement for greater safety in all industries and that the value of this work has been great and cannot be measured in dollars.

Among the results of this increasing safety and health are the saving of life among miners who received first-aid treatment; the enactment of State laws to increase safety, prevent accidents, and lessen waste; and the tendency to demand more efficient inspection in mining and other industrial establishments.

The Bureau has been responsible for a revolutionary change in the use of explosives in coal mines. It pointed out the dangers attending the use of black powder in mines that were gaseous or filled with coal dust, and urged the substitution of what it termed 'permissible explosives,' those that had successfully passed severe tests. In the year 1908 only 2,000,000 pounds of these permissible explosives was used in the coal mines of the United States. In 1915 the amount of permissible explosives sold was 27,350,000 lb., or nearly 14 times as much as in 1908.

By calling attention to the possible dangers attending the use of electricity in mines the Bureau has led manufacturers to devise safer types of apparatus, especially electrical switches and motors, that can be used in gaseous atmospheres without danger of causing explosions by sparks or flashes. Also, the Bureau's activities have led to the manufacture of approved types of hand and cap lamps for miners, by which mining is rendered safer. Several States have followed recommendations for enacting stricter laws regarding electrical equipment in mines. Recently the Bureau has been investigating gaso-

line and storage-battery locomotives for mine haulage.

In co-operation with the Public Health Service the Bureau has investigated the health conditions in certain of the metal-mining districts where miner's consumption, caused by the breathing of silicious dust, is prevalent and where the death-rate from this disease was causing alarm. It has shown the operators and miners the injurious effects of breathing this dust and how, by the proper treatment of the rock-dust, deaths from this cause may be greatly reduced, if not entirely stopped. The Bureau has pointed out how the homes of miners can be made more comfortable and more sanitary, and has already witnessed its recommendations adopted by mining companies and construction concerns.

Some direct results of the safety movement and the workmen's compensation laws have been a saving of thousands of men to their families, a tremendous reduction in the amount of suffering through lessened injuries, and, where men have lost their lives through the hazards of industry, an adequate compensation to sustain the widow and the orphans.

The Bureau sends out to the men in the mines pamphlets called 'miners' circulars,' which tell of the dangers in the mines and the precautions a man should take to avoid injury and disease. The Bureau is issuing a number of these safety-papers for the especial benefit of foreign-born miners, each paper being printed in a foreign language with the English translation on the facing page, so that the miner is enabled to learn English at the same time that he learns the safety-lessons.

Since the Government began its educational work of demonstrating the use of rescue apparatus and of training miners in methods of recovery work and administering first-aid to those injured by accidents, more than 40,000 miners have been trained by the crews of the Bureau's stations and cars. Moreover, as a result of this educational work and of the efforts of men who had received training, nearly 1000 men have been rescued from mines after explosions or other disasters. It is estimated that at more than 1000 mines there are now well-equipped and trained rescue-crews. Interest in first-aid methods is being stimulated by contests between teams representing different mining companies and by teams representing miners' organizations in different States.

The additional safety-stations to be provided under the terms of the act approved by Congress in 1915 will enable training to be given in districts where such training and proper facilities have long been requested.

The Bureau's engineers have been highly successful in developing devices for preventing dust explosions in coal mines. Dusts from hundreds of mines in different coal-fields have been studied and their relative inflammability has been determined. In addition, suggested methods of rendering coal-dust harmless have been tested at the experimental coal mine.

Since the Bureau was created it has kept careful statistics of the number of men killed in coal mines, metal mines, and quarries throughout the country. These

statistics now cover a period of five years and show in the first year, 1911, a total of 3539 killed in all of the coal and metal mines and quarries of the United States, with a death-rate of 3.52 for every 1000 employed. There has been a steady decrease not only in the number of men killed but also in the death-rate. For the year 1915, there were 2970 men killed with a death-rate of but 3.01 for each 1000 employed.

The greatest progress has been made in coal mining. The statistics for the year 1915 show these important conclusions. The actual number of men killed was the lowest in the last eight years. The death-rate for each 1000 men employed was the lowest in the last 16 years. The number of tons of coal produced for each miner killed was the largest in the entire history of coal mining in the United States.

While the year 1915 was the safest ever known in coal mining in the United States, the figures for the first eight months of 1916 indicate that the 1915 record will be eclipsed. For these eight months of this year there are 72 less fatalities than for the same months of 1915, a reduction of 5% from the record of that year. The United States today mines 40% of the world's output of coal, or as much as Great Britain and Germany combined; and its coal mines employ more than three-quarters of a million men.

Recognizing the need of reliable figures of deaths and injuries in the mineral industries, as a basis for determining the hazards, and the rules and regulations needed for safety, the Bureau compiles and publishes annually accident statistics for coke-ovens, ore-dressing plants, and smelters, as well as quarries. Under a co-operative arrangement with all State coal-mine inspectors it publishes a monthly report of coal-mine fatalities, showing their number, cause, and distribution by States. Recently the Bureau published a compilation of all coal-mine fatalities (over 50,000) reported by State mine-inspectors since the beginning of inspection by each State, the figures covering the mining of more than 89% of all the coal produced in the United States since 1807.

MORE EFFICIENT METHODS. Investigations of the problems of miscellaneous mineral technology include safety and efficiency in the preparation and use of the minor metals, rare metals, and various minerals used in the arts. In these investigations especial attention has been given to the possibility of eliminating some of the great waste that takes place and, incidentally, to increasing the efficiency of manufacturing processes and the substitution of domestic for imported products. These investigations have already demonstrated the extent and variety of the losses occasioned by methods in current use.

The feldspar, mica, and kaolin resources of the Appalachian region, and the kaolin resources of the Coastal Plain region of Georgia and South Carolina have been studied with reference to the needs of American potters. The results show that American feldspar is equal, if not superior, to that obtainable elsewhere, that many of the kaolin deposits of the southern Appalachian region yield china clay that is remarkably white and equal in quality

to any imported, and that by a simple and inexpensive treatment under careful control, the immense deposits of kaolin in the southern part of the Atlantic Coastal plain may be made available for china and other white ware.

An investigation of the fuller's earth industry of the country has been instrumental in bringing about a great increase in the production and utilization of domestic earth during the last few years.

In co-operation with the American Institute of Metals and the chemical department of Cornell University, the Bureau of Mines has studied the manufacture of brass and other non-ferrous alloys, with especial reference to preventing the known large waste of metal in both dross and fume, that amount to at least \$2,000,000 a year. Methods of reducing this loss have been pointed out and the development of an efficient type of electric furnace seems assured.

Probably the most striking of the mineral-technology investigations has been that dealing with radium. Through the co-operation of the National Radium Institute a plant was built at Denver for producing radium from the carnotite of Colorado. This plant has been in successful operation for nearly three years, and has produced six grams of radium, which is to be used in the treatment of cancer and malignant tumors. This work has shown that the price formerly paid for carnotite was entirely out of proportion to the value of the mineral contained, and that from Government-owned ore, at least, radium can be supplied to the hospitals of the Army, Navy, and Public Health Service at a cost not exceeding \$36,500 per gram, or one-third of the price that had been asked by foreign producers.

Incident to this work methods for determining radium, concentrating the low-grade carnotite ores, and extracting uranium and vanadium from carnotite were developed.

The metallurgical investigations of the Bureau have been confined chiefly to the smelter-smoke problem, the treatment of low-grade and complex ores, and to the safety and health of employees at blast-furnaces and steel works.

In its endeavor to find ways of lessening damage to vegetation and to animals and of recovering and utilizing substances being wasted in smelter-smoke, the Bureau co-operated with the Selby and the Anaconda smelter commissions. The report of the Selby commission, published as a bulletin by the Bureau of Mines, has received much attention, and the methods of procedure described are being followed in other metallurgical-smoke investigations both in this country and abroad. The Anaconda commission is continuing its investigations. Each commission has been entirely independent of the Bureau of Mines, but the Director of the Bureau has served as a member of each, and the Bureau has co-operated in the investigations. Especial attention has been given the removal of sulphur from smelter-gases.

Investigations of methods of treating the low-grade and complex ores of Utah and adjacent States are show-

ing what new methods are needed or how old methods should be improved to treat millions of tons of ore that lie unworked because of the lack of efficient and profitable methods for saving the contained metals.

Summarized, the principal results of this work have been the development of a brine-leaching process for extracting lead from low-grade and complex ores; the development of a process for the recovery of lead and zinc from lead-zinc sulphides; the application of flotation to the recovery of the lead in carbonate ores; the development of a process for the recovery of zinc from low-grade, complex ores of that metal; and the development of a process for the production of zinc-dust from solutions of zinc.

The investigations of fuels and mining equipment have thrown light on the process of combustion in furnaces and gas producers, and have led to the design of more efficient boilers. The development of an improved type of breathing-apparatus for use by rescue-men in mines after explosions or fires, and the demonstration of the precautions that should attend the use of gasoline-locomotives in mines, are results of this investigation.

The petroleum investigations have shown that the enormous wastes of natural gas and petroleum which have attended the development of gas and oil-fields have not been confined to the gas that escaped into the air, to the losses by fires, and to the evaporation of oil in reservoirs or tanks. The unseen wastes underground through improper methods of drilling and casing wells, by which gas has dissipated into porous beds from which it cannot be recovered, or water has drowned out oil-fields before more than a small proportion of the oil has been obtained have annually resulted in decreasing our national wealth by many millions of dollars.

The Bureau of Mines has shown how these wastes in production can be largely eliminated by improved methods of drilling, especially by sealing porous beds with fluid-mud and by making suitable provision for the control of high gas-pressures. Also, the Bureau has been instrumental in increasing efficient utilization of natural gas, petroleum, and products, through its studies of the recovery of gasoline from natural gas, and the attention it gave to the development of the Rittman 'cracking' process for obtaining gasoline, benzene and toluene from petroleum.

MINING REGULATIONS. In the endeavor to promote safety and efficiency in mining by aiding State legislatures to enact more effective laws, the Bureau of Mines has examined all Federal and State statutes relating to mines and mineral property, and all decisions of courts of last resort in which these statutes have been construed or interpreted. A large bulletin recently issued embraces all the United States mining statutes and is annotated by references to all important decisions. Also, the Bureau is publishing at regular intervals digests of decisions bearing on mining that have been handed down by State and United States courts of last resort. Still another work has been the publishing of proposed rules and regulations for metal mines. A proposed code of

rules to govern the installation of electrical equipment in mines is now in course of publication.

TRAINING OF ENGINEERS. My statement of the work the Bureau of Mines is doing for safety and efficiency in the mineral industries would be incomplete if I did not call attention to the increasing importance of the Bureau as a training-school for engineers and chemists. The services of the expert chemist and engineer are in greater demand today than ever before. This fact has been brought home to me by the number of men who have recently left the Bureau to engage in private work at salaries far larger than the Government now pays. It seems to me that, in considering Federal aid to mining efficiency, we should endeavor to realize the profound influence that these men will exert in making our industries safer and more efficient.

FEDERAL APPROPRIATIONS. For the present fiscal year the appropriations for the Bureau's work are more than 100% larger than for the fiscal year 1911, the first year of the Bureau's existence. Still larger appropriations were virtually promised by Congress when it voted early in 1915 to establish and maintain ten new mining experiment stations and seven new mine-safety stations.

The specific purpose of the appropriations made has been largely influenced by the earlier investigations dealing with mine explosions. Thus, in 1911, 60% of the funds appropriated were for investigating mine accidents, 20% for testing fuels, 13% for general expenses, and 7% for inspecting mines in the Territories and making public reports. As a result, most of the investigations made hitherto have been incidental to mine-safety work and related to coal mining rather than to metal mining.

The appropriations for the present fiscal year provide \$100,000 for mining investigations, and \$70,000 for investigations of petroleum and natural gas. These funds will enable the Bureau to extend its activities in fields that previously have received only incidental attention.

PROJECTED ACTIVITIES. The 10 new mining-experiment stations are to be administered by the Bureau of Mines and are to be located at points in the mining regions where work can be done to best advantage, plans have been perfected for the immediate establishment of the first three of these stations—one in Alaska, one in the Pacific North-west, and one in the South-west.

Also plans have been prepared for developing the 10 stations into individual centres of research, each attacking those problems of most interest to the locality in which it is situated.

One of the great needs of the mining industry is the development of electro-metallurgical processes for the reduction of the base metals. In certain parts of the country, as the Pacific North-west, vast water-power is available and electricity can be generated at minimum cost. There a satisfactory electro-metallurgical process would make commercially profitable the working of millions of tons of mineral deposits that cannot now be worked at a profit.

Of the projected investigations none is of more im-

portance than the study of ventilation in metal mines. Preliminary work and the data obtained in related investigations have shown the scope and character of investigation needed and the Bureau hopes to be able to resume the work in the coming fiscal year.

A study of subsidence, earth-pressures, and roof-supports in mining promises results of great importance to mining and to various engineering enterprises.

In tunneling under bodies of water or in shaft-sinking through water-bearing ground special methods are required. Many cities are driving tunnels under bodies of water for transportation purposes or for water supply, and the Bureau has been asked to give advice, more especially at Milwaukee and Cleveland, where tunnel disasters have occurred. If the funds are made available the Bureau will take up this work, and also study methods of insuring better ventilation in tunnels.

In investigations relating to the iron and steel industry the Bureau will endeavor to develop methods of producing iron and steel with a smaller consumption of fuel, to discover and make available materials now imported, and to develop processes for recovering useful substances from waste products. Among these proposed studies are: An investigation of blast-furnace coke; the use of an oxygen-enriched blast at furnaces; the feasibility of recovering manganese and other ferro-alloys from the wastes of the metallurgical industries; determination of the amount of potash and phosphorous salts available theoretically in the fumes, gases, and slags of the industry, and the practicability of recovering them on a commercial scale.

MINING TERMS. In any proposal recommended as a basis for mining laws that seek to increase safety or efficiency, it is essential that the terms used shall be precise and have more than a local use, or that the terms be carefully defined in the act itself. The confusion and uncertainty caused by using terms of varying significance without defining them is well illustrated in the legal decisions constraining the Federal mining-land law. Recognizing the need of a comprehensive glossary that shall define mining terms with particular reference to their usage in the United States, the Bureau of Mines is preparing a glossary that will contain all available terms used in coal and metal mining; quarrying, and metallurgical practice; geological terms as related to mining; names and definitions of the commoner useful minerals; and also terms used in the oil and gas industry. The work has progressed to such an extent that about 10,000 terms have been arranged alphabetically, and work is being conducted to verify terms selected from former glossaries and to add new terms.

AFTER THE WAR. American industries have met and overcome foreign competition in the markets of the world by reason of the abundance of our natural resources, the ingenuity of our inventors, and the use of improved machinery by which higher wages paid here are compensated by the greater value of the output per man. Today Europe is being forced to increase the per capita output of its artisans, to 'hustle', to use labor-saving machinery

on an unprecedented scale, and to make a larger use of female labor in many occupations. After the War many of the millions now under arms or engaged in making military supplies will be employed in the industries of peace, much of the labor-saving machinery will not be scrapped but will be used in making products that will be needed, and the increased efficiency developed through the necessities of war may be expected to persist for an indefinite period.

In the readjustments that will follow the coming of peace, the American producer will have to consider not only the mineral industries of a different Europe, but also the effect of these differences on the output of mines and works in Canada, Mexico, South America, Asia, and Africa. Clearly some of our old standards of trade are liable to disappear; new conditions will create new problems.

It seems to me that the chief needs of the United States, if it is to meet these new conditions successfully, are a wider and deeper co-operation among our industries, an elimination of factionalism and sectionalism, and the growth of a desire to work together for the common good.

Inasmuch as no plan of co-operation can be most effective unless based on willingness and desire rather than on compulsion, and as everybody can aid in some way, I ask the members of the American Mining Congress to endeavor in their undertakings to bring about the substitution of what has been termed "co-operation in competition" for that intense and selfish competition which has led to ruthless waste of our natural resources and shocking disregard of human life. The Bureau of Mines has sought and seeks your co-operation in all its efforts to benefit the mineral industries and the men who labor in them. Nothing has given me greater pleasure than the manner in which the American Mining Congress and other organizations, as well as mining companies, and miners, engineers, and chemists have responded to that appeal, and I gladly take this opportunity to express my gratification.

But, after all, the work for greater national efficiency is hardly more than started; what remains to be done is far larger than what has been accomplished, and for this reason I hope that you will continue to aid the Bureau in its investigations, offering suggestions or making criticisms as you see fit, and adopting such of its recommendations as you find practicable. Federal aid to efficiency cannot accomplish what it should unless you feel that the Government is endeavoring to help you, and the Department of the Interior and the Bureau of Mines cannot do what they wish to do unless you perceive that behind their efforts to aid efficiency in mining is the desire to advance the welfare of this country and through that to contribute to the betterment of all mankind.

THE United States leads the world in the production of tungsten ores and alloys of tungsten. Before the War, Great Britain controlled the tungsten production and Germany the manufacture of tungsten alloys.

FIG. 4. MAIN SHAFTS, COMPRESSOR-HOUSE, COARSE-CRUSHING PLANT, AND STORAGE-BINS OF INSPIRATION CONSOLIDATED COPPER CO.

Automatic Electric Hoist at the Inspiration Mine

By H. Kenyon Burch and M. A. Whiting

*One of the advantages of electric drive is the ease with which motors can be controlled automatically. In many cases some features of the control are automatic—for example, the rate of acceleration may be limited automatically or the equipment may be stopped automatically at the limit of travel—but the equipment is ordinarily started and stopped by hand. In other cases the motion of the machinery is utilized to start, control the speed, and stop the motor automatically, independently of any operator.

A considerable number of the large mine-hoists now in use have automatic features, particularly protective devices against over-winding, and, in some types of electric hoists, devices for preventing excessive acceleration or retardation. The large automatic hoists discussed in this paper, however, are completely automatic, that is, capable of making their trips without the presence of an operator at the control-levers.

According to circumstances, various advantages may be obtained by automatic control, chief of which are decreased power consumption, increased precision and safety of operation, and decreased cost of attendance. The first step in the analysis of a prospective automatic mine-hoist is to determine whether automatic operation is feasible at all. If men are to be hoisted, or skips changed at levels, the attention of an operator is re-

quired; but under some conditions it may be entirely practicable and advantageous to build the equipment so that, while provision is made for hoisting men or changing levels, ore can be hoisted automatically from any one level. If, however, an operator's attention is required every few minutes for changing levels, hauling men or drills, or for other work requiring hand-control, it is obvious that automatic operation between times will not be of any practical benefit.

For a slow hoisting-speed it may be possible for the skip or cage to pass through the dumping-point at full speed, and a sufficiently accurate stop may possibly be obtained automatically by cutting-off power and applying the brakes at full speed. In this case, either a shunt-wound direct-current motor or an induction-motor may be used. A number of slow-speed automatic hoists are arranged in this manner, and are driven by induction-motors. One equipment of this type used in mining is the inclined hoist for hoisting concentrate at one of the mills of the Arizona Copper Co. This hoist has a rope-speed of approximately 275 ft. per minute.

For higher rope-speeds, at least over 400 ft. per minute, it is necessary to consider carefully the speed-characteristics obtainable from the type of drive proposed. For these higher rope-speeds, it is necessary to slow-down before entering the dumping-horns. Furthermore, the speed about midway in the dump must usually be reduced below the maximum safe speed entering the dump. A reasonably accurate stop is always

*Abstract from *General Electric Review*, a paper originally presented at the September meeting of the American Institute of Mining Engineers.

required; in some cases a total variation of 2 or 3 ft. might not prove prohibitive, but in other cases the stop must be more accurate. For reliable operation, it is nearly always imperative that the automatic-control system shall act in like manner irrespective of load, that is, that the rate of retardation and the position of stopping be nearly the same whether the skip comes up loaded or empty.

There is only one class of motive-power that is inherently suited for automatic operation at high rope-speeds, namely, the direct-current shunt-wound motor with voltage control. The speed-torque characteristics for an equipment of this character are represented in Fig. 1. These curves are typical of this class of equip-

FIG. 1. TYPICAL SPEED-TORQUE CURVES FOR DIRECT-CURRENT MINE-HOIST WITH GENERATOR FIELD-CONTROL.

ment, although the exact slope of the curves will vary slightly in individual cases. Curve 1 shows the characteristic on the lowest, and curve 5 the characteristic on the highest, speed position of the controller for the case selected. The intermediate curves represent three controller points arbitrarily selected out of a total of 30 or more. It will be observed that these curves are nearly, but not quite, parallel. That is to say, the increase in speed in passing from full load to no load is approximately, but not exactly, the same for the various positions of the controller. The deviation from parallelism is due to the effect of armature reactions in the generator and hoist-motor, and may be somewhat different for different cases; but its effect is negligible.

The net advantages (for the purpose of automatic hoisting) obtained by this system of drive are as follows:

As the hoist-controller is moved back toward the off-position the hoist is retarded. In case the net rope-pull is sufficient and the stored energy of the moving system is not too great, the hoist motor simply drops back in

speed to correspond to the reduced generator voltage obtained on the intermediate position of the controller. If, however, the net rope-pull is low (particularly with empty skips in balance), and if the stored energy of the moving system is high, the hoist-motor will invert, momentarily, and will act as a generator, returning power to the motor-generator set. This effect is represented in Fig. 1 by the extension of the curves below zero-torque. In this manner, if the controller is moved toward the off position more rapidly than the hoist tends to come to rest under the influence of the load, the hoist-motor forcibly retards the hoist. If the controller is moved back at the same rate in both cases, the hoist will be retarded to nearly the same speed, and in nearly the same time, irrespective of load in the skip.

It is fairly obvious that the steam hoist is unable to approach closely the speed conditions described. The steam hoist, of course, is capable of retarding a load by working against the steam or compression, but the vital points in relation to automatic hoisting are: (1) for the same throttle opening and cut-off, the speed will vary widely with variation in load; and (2) if the throttle is partly closed or the cut-off advanced to a point at which the skip will enter the dump at a suitable reduced speed, the engine will exert only a slight retarding-torque (if any) to help retard from full speed to the reduced speed at which the engine tends to continue. Most of the retardation must therefore come from the load, which is variable or may even be negative. Furthermore, with a partly closed throttle the final speed at which the engine tends to continue will vary widely with variation in load.

The induction-motor hoist, in its relation to automatic hoisting, has somewhat the same characteristics as the steam hoist. Fig. 2 represents the speed-torque char-

FIG. 2. TYPICAL SPEED-TORQUE CURVES FOR INDUCTION-MOTOR DRIVEN MINE-HOIST.

acteristics of a typical mine-hoist induction motor. In a direct-current hoist, a given retardation can be accomplished in a certain time and distance by the same manipulation of the control, irrespective of the load

hoisted. In a steam or air hoist or an induction-motor hoist, a like retardation of different loads requires different manipulation of the control.

These characteristics indicate, and their further consideration confirms, the conclusion that high-speed mine-hoists that are to be operated automatically must be, in almost all cases, driven by direct current.

When the arrangement of its main shafts was under consideration by the Inspiration Consolidated Copper Co., a concurrence of several conditions indicated the possibility of effecting a saving by hoisting the ore automatically. These conditions were as follows: (1) A direct-current equipment was necessary in any case, as a motor-generator set was required for the fly-wheel equalization as provided in the power contract with the U. S. Reclamation Service. [From hydro-electric power generated at the Roosevelt dam.—EDITOR.] (2) The ore was all to be hoisted from one level. (3) Drills, timbers, supplies, and waste were to be hauled through a drift opening. (4) Men were to be hauled on a separate hoist exclusively. (5) On account of the moderate depth and rope-speed only a moderate retardation effort would be required.

Two three-compartment shafts have been sunk for two independent balanced hoists, each hoist being adequate in an emergency to keep the concentrating-plant operating at practically full capacity. The third compartment of one shaft contains a double-deck man-cage, operating against a counter-balance weight, and the third compartment in the other shaft carries this counter-weight, together with air-pipes, power-cables, etc. Skips carrying $12\frac{1}{2}$ tons are used, and the ordinary hoisting schedule for which the equipment was designed called for an output of 10,000 tons, with a maximum capacity of 14,000 tons, in 14 hours. The hoists are at one end of the compressor-house. No. 2 hoist, in the background in Fig. 3,

FIG. 3. MAIN HOISTS AT THE INSPIRATION.

handles the skips in the east shaft, which is nearest the compressor-house. No. 1 hoist, in the foreground, handles the skips in the west shaft, the ropes from No. 1 passing above No. 2 hoist over idler-sheaves on the upper deck of the east head-frame, thence over the sheaves on the west head-frame. Fig. 4 shows the arrangement of shafts and head-frames in relation to the compressor-house.

The hoists are duplicates, each consisting of one fixed

and one clutched drum, each 10 ft. diam. by 65-in. face, grooved for 1000 ft. of $1\frac{3}{4}$ -in. rope in one layer. The brakes and clutches are air-operated with oil-cataracts and floating-levers, and the automatic-control system was so designed that the brake-engines could be made practically standard (Fig. 5). The hoists were designed

FIG. 5. DRUMS AND BRAKES OF ONE MAIN HOIST.

and built by the Nordberg Manufacturing Co. and the electrical equipment by the General Electric Company.

Each hoist is driven by a 580-hp., 575-volt, 264-r.p.m. shunt-wound motor through a flexible coupling and Falk gears. Power is supplied to the hoists by a 750-r.p.m. fly-wheel motor-generator set, consisting of one 850-hp., 2300-volt, 25-cycle induction-motor, two 500-kw., 575-volt generators, one 20-kw., 125-volt exciter, and a 19,700-lb. 112-in. diam. steel-plate fly-wheel. Each hoist-motor is connected separately to one of the generators and controlled by varying the field of its generator. The fly-wheel is not in any way necessary to the control or automatic operation of the hoists. Its function is to eliminate the peak-loads from the power-system. The control for equalization of the power demand follows along standard lines, using a liquid slip-regulator for varying the speed of the fly-wheel set by varying the resistance in the secondary circuit of the induction motor (Fig. 6).

The depth, from the dump to the chairs under the loading-pockets, is 630 ft. in each shaft; from the collar to the chairs, 557 ft. The rope-speed is approximately 750 ft. per minute.

Before beginning automatic operation it is necessary, of course, that each hoist be properly clutched-in for the loading-level, with one skip in each shaft resting on the chairs below its loading-chute. It is not important which skips are on the chairs, provided, of course, that the operator obtains a 'release' of skips in both shafts before starting the automatic operation. He then introduces the automatic control by closing two small control-switches and locking in two levers, all on the operating-platform. This does not, of itself, start the automatic operation, so that the hoists may be left standing in this manner indefinitely. To start the automatic operation, a master-controller is thrown to the automatic running position, and left there as long as automatic hoisting

continues. According to the positions in which the skips have been resting, one hoist or the other will start. Say, for example, No. 1 hoist starts, hoisting its south skip. The closing of the master-controller just mentioned energizes a small pilot-motor that moves No. 1 hoist controller gradually to the full-speed position in one direction. As No. 1 controller starts away from the off position,

FIG. 6. LIQUID SLIP-REGULATOR FOR REGULATION OF INPUT TO FLY-WHEEL SET.

tion, it simultaneously energizes No. 1 generator-field and actuates a pilot device that releases the brakes on No. 1 hoist. As the controller moves farther toward the full-speed position, it gradually builds-up the generator voltage, thereby accelerating the hoist to full speed.

Toward the end of its trip the travel of No. 1 hoist actuates a pilot-motor that moves No. 2 hoist-controller gradually to the full-speed position in one direction, thereby accelerating No. 2 hoist in a similar manner, to hoist its north skip. Shortly before its skip enters the dumping-horns, the travel of No. 1 hoist, by means of cams, one of which is geared to each drum, moves No. 1 controller gradually toward the off position. This gradually decreases No. 1 generator voltage, thereby retarding No. 1 hoist, and just as its north skip is about to land on the chairs, No. 1 controller comes into the off position. This completes the retardation and automatically applies the brakes. No. 1 hoist stands at rest while No. 2 is hoisting its north skip. Toward the end of its trip, No. 2 hoist energizes the pilot-motor for No. 1 controller so as to start No. 1 hoist in the opposite direction, that is, to hoist its north skip. No. 2 hoist comes to rest in the manner described for No. 1, and rests while No. 1 is hoisting its north skip. Toward the end of its trip, No. 1 hoist energizes the pilot-control to start No. 2 in the opposite direction, that is, to hoist its south skip. The sequence continues in this manner until stopped by the operator, as described later.

A loading system is used underground by which the skips are automatically loaded with a pre-determined weight of ore per trip. The reduction of the attendance required at the foot of the shaft contributes materially to the advantages of automatic hoisting. The automatic loading system can be thrown out of engagement in either shaft so that the hoists may be operated either

automatically or by hand, for purposes of inspection or adjustment, without hoisting any ore.

To obtain a more rapid operation of the hoists, that is, a greater number of trips per hour, when operating automatically a control-switch may be thrown, by which each hoist will be started earlier in the trip of the other hoist, thus over-lapping to a greater extent the trips of the two. If it is desired to run the hoists automatically at fewer trips per hour than normal, this is done by introducing resistance permanently in each generator field-circuit, to give a rope-speed lower than normal.

When the details of design were first considered, one of the chief problems was the arrangement of the control so that the transition from hand to automatic operation, and more especially the transition from automatic to hand operation, might be made without risk or delay, and in a manner easily remembered by any operator acquainted with the equipment. To this end the levers on the operating platform which work the hoist-controllers and brakes for hand control are not disconnected from the controllers or brake-engines when running automatically. Consequently, when the automatic pilot-devices are cut in, and the hoists are operating automatically, these levers move back and forth, as if the hoists were being controlled by hand by invisible operators. When, therefore, the transition from automatic to hand operation is made during a trip, the brake and controller-levers of both hoists are in the correct positions and properly in engagement for hand-control.

The automatic operation can be interrupted at any time during a trip. This is done most easily by throwing the master-controller for automatic operation to the off position, which causes any trip which is under way at the time to be completed automatically, dumping in the usual manner, but prevents the next trip from starting. If the hoists are then left standing, and not operated by hand, all that is necessary to start automatic hoisting again is to throw the master-controller to the automatic running-position (Fig. 7).

Before the construction work at the foot of the shafts and in the bins in the tippie had been completed in detail, it was necessary occasionally to stop an automatic trip without letting it dump. In such an event, or when necessary for any reason to transfer to hand-control before completing a trip, the master-controller for automatic hoisting is thrown to the off position. Without disconnecting or unhooking any other parts the controller lever of the hoist which is running may then be pulled back to the off position by hand, and as the controller comes into the off position the brakes will set automatically. It is now possible to leave the pilot-control of the brakes connected in service, so that the brakes will release and set automatically, as the controller is moved by hand from or to the off position. Or, if necessary on account of the character of hoisting to be done, the automatic pilot-control of the brakes can be cut out, in which case brakes and controller will be controlled separately by hand.

Under all conditions (except when making adjust-

ments in the manner described later), the cams on each hoist-controller remain connected mechanically to the hoist-drums. This cam mechanism thus serves two purposes: (1) in automatic operation it provides the automatic slow-down and stop; and (2) in hand-operation, if the operator does not begin retardation at the proper point, this mechanism will retard the hoist in practically the same manner as when hoisting automatically, thus providing protection against overwinding when operating by hand.

The protective system resembles those of a considerable number of large direct-current mine hoists, of the

FIG. 7. DEPTH INDICATORS AND AUTOMATIC-CONTROL SYSTEM FOR MAIN HOISTS.

same general type (except the automatic operation) as the Inspiration hoists. In the latter, as has just been noted, the automatic control-system provides against over-winding in hand-operation. An additional set of emergency-limit switches is used, which gives similar protection in case of failure of the automatic control. During hand-operation there are effective, therefore, two complete sets of protective devices against over-winding. For each hoist a hand-operated emergency-switch is provided on the operating-platform, and a similar emergency-switch is located at the foot of the corresponding shaft, by means of which either or both hoists may be stopped quickly from the operating-platform, or the foot. Without appreciable complication, additional emergency-switches may be installed at other points, if desired.

The operation of any one or more of these emergency devices cuts-off power from the hoist and makes an emergency application of the brakes. An emergency, which affects one hoist only, acts on the power and brakes of that hoist only. The failure of excitation or alternating-current power, which affects both hoists, cuts-off power and makes an emergency application of the brakes simultaneously on both hoists.

When unclutching for changing levels, and when taking up stretch of ropes, the adjustments are taken care of as follows:

On the Inspiration hoists it has been the custom, whenever the hoists are to be idle a whole shift, to bring both skips to the collar of the shaft, in order to save

rusting of the ropes. This is done by unclutching just as in any ordinary hoist with one fixed and one clutched drum. If desirable for any reason, either hoist may be run by hand-control either out of balance or clutched in for balance to operate from other levels than the regular loading-level. When clutching or unclutching, the adjustments of the automatic control-system are not touched.

If the shafts are sunk to the ultimate depth contemplated, and the present loading-stations abandoned, the control can be re-adjusted to operate automatically from the increased depth. Without changing the adjustment of the control-equipment, it is not possible to operate automatically from levels differing considerably from the normal level for which adjustment has been made, but the system is capable of modification so as to hoist automatically in balance from any level to the dump, without re-adjustment, all the adjustments being taken care of automatically by clutching-in at the desired level.

Stretch of ropes is taken up in a simple manner which itself is semi-automatic and does not require any measurements. The first time it was necessary, the stretch was taken up on both ropes of one hoist in about 15 min., at the end of which all adjustments were in shape for hand or automatic operation. The method is as follows:

The hoist is run into an automatic stop with the skip on the clutched side resting on the chairs. (This is effected by the cam which is geared to the clutched drum). The controller and cams are now in the proper position for an automatic stop on this side but the rope on this side has unwound farther than normal by an amount equal to the stretch or slack which it is intended to take up. This cam is now uncoupled, but the other cam is left coupled. The hoist is now moved by hand-control just far enough to wind up the estimated amount of slack, and the cam on this side is then coupled up to the clutched drum. This operation takes up the slack on the clutched side and transfers it to the fixed side. The hoist is now run, in balance, into an automatic stop on the fixed-drum side, which lands the skip on the fixed-drum side on the chairs, and brings the skip on the clutched side into the dump. The cam on the fixed side is now uncoupled, and before moving the hoist to take up slack, the other drum is unclutched, so as to leave its skip in the normal position in the dump. The fixed drum is then moved sufficiently to take up all the slack on that side, that is, the stretch of rope on that side plus the slack transferred to that side by taking up the stretch on the clutched-drum side just previously. The cam is then coupled up to the fixed drum and the other drum is clutched-in, which completes the adjustment of both ropes and cams and leaves the hoist ready for operation. It is necessary, of course, not only to take-up stretch on each side, but also to clutch-in at the proper level. During the foregoing procedure, after unclutching one drum as described, the same movement of the other drum which takes up the slack also makes the necessary correction for level.

The east shaft was ready for operation before the construction work had been completed in the west shaft. The ropes were put on No. 2 hoist, and for purposes of test and for a thorough try-out of the system, both hoists were operated automatically, No. 1 hoist running automatically as if in actual service, but without any ropes on the drums.

Both ropes were on No. 2 hoist and both skips were hung in the east shaft by the morning of July 25, 1915. During one shift on that day, after marking the ropes and the drum-flanges, the automatic control and depth indicators were coupled to the drums, the shaft and tippie clearances were checked, cams adjusted for automatic retardation and stop, and 18 skips of ore hoisted by hand-control, using the cams for automatic retardation but not using complete automatic operation. The following day, between 8 a.m. and noon, adjustments for complete automatic operation were made, and 44 loaded skips were hoisted automatically. The adjustments were refined somewhat at a later date, but those made during the first 45 minutes of automatic operation worked well.

The same morning in which the equipment first operated automatically, the accuracy of stop was observed for 12 consecutive trips, that is, six trips each way. The total variation between maximum and minimum was 4 in. of rope-travel. After a few weeks of intermittent operation, similar observations were taken. In 20 consecutive trips (10 each way), the total variation between maximum and minimum was only 1.5 in. of rope-travel in one direction and 1.25 in the other. During this time the ore hung back in the loading-pockets on one side, so that six of the trips included in the above figures were made empty. It is significant that this variation of 1.5 in. is only 1% of the distance traveled per second at full speed of the hoist.

To operate two hand-controlled hoists, either steam or electric, of the size and importance of these, would require at least two operators per shift; and according to practice in some mining districts, an oiler would be employed in addition to the two engine-men. For the operation of these two automatic hoists there is required only one operator, who is able to attend to the oiling and to whatever hand-operation of either hoist may be necessary on his shift.

In conclusion it may be said that the application of automatic mine-hoists will always be limited by the fact that operation cannot be truly automatic, except where the conditions of hoisting are reasonably uniform. In other words, where under prevailing conditions, the attendance of an operator is required practically continuously throughout the shift in order to change levels, hoist or lower loads out of balance, or hoist men, it is impossible to realize any practical advantages by operating automatically during the short periods of hoisting ore regularly from any one level. On the other hand, entire uniformity is not necessary in order to make automatic operation practicable. As an illustration, consider the case of a main hoist serving a few levels, and

an auxiliary hoist in the same hoist-house handling all men, timber, supplies, waste, etc., for all the levels served by the main hoist. Conditions of operation may possibly be sufficiently favorable so that if the main hoist is arranged for automatic operation (or for semi-automatic control from the level-stations by the skip-tender), the operator for the auxiliary hoist will be able to take care of the hand-operation required on the main hoist. It may reasonably be anticipated that from time to time various mine-hoisting problems will arise in which the possibilities offered by automatic hoisting should by no means be dismissed without investigation.

Flotation Oil From Sage-Brush

The clearing of land of its sage-brush is ordinarily accomplished by means of a tractor pulling a frame made of railroad rails. This breaks off the bushes so that they can be collected and hauled to a central point. With the average 4-ft. stand of brush in south-eastern Nevada the yield per acre is about 7 tons of brush. The cost is about \$1 per ton for cutting and collecting the brush to a central point. The cost of destructive distillation of hard wood is in the neighborhood of \$8 per cord (4000 lb.) of wood, or about \$4—possibly \$5 per ton of wood. The sage-brush is more bulky than the wood, and it is best to count on a distillation cost of \$5 per ton. That would make the total cost of treatment of each ton of sage-brush about \$6 with a yield of 80 lb. of tar. This would mean 10 gal. produced at a cost of \$6, or \$0.60 per gallon, or 7.5c. per pound. This is high but is comparable with the present price of pine-oil, of which sage-brush oil seems to be the full equivalent, if not the superior. With most ores, less than 0.5 lb. of sage-brush oil should be needed per ton of ore.

There is one other source of income from the products of the sage-brush, namely, potash, which in carefully burned brush ashes amounts to 15 to 20% of the total weight. Most of this was soluble in water.

About 10,000 gal. of steam-distilled pine-oil is being used every month in the United States for flotation purposes and more would be used if the price were lower. If sage-brush oil could be produced for 40c. per gal. it is probable that the market would jump to at least 1000 gal. per day. With this would be produced 3000 to 4000 lb. of potash, an amount which is much less than 1% of the total consumption in the United States. If the oil could be produced for 25c. per gal., there is no reason why its use should not amount to 10 times the consumption of the oil at a 40-cent rate.

AT THE MILL of the Babilonia mine, Nicaragua, lime costs from \$40 to \$50 gold per ton delivered at the mine. It is paid for according to its content of available CaO, which seldom is more than 40%. Costs are high owing to scarcity of labor and the present high price of supplies, especially zinc and cyanide. The tonnage for July has been increased from 1525 tons to 1800 tons and it is expected to remain at that figure.

The Lead Mines of Washington County, Missouri

By Sydney H. Ball

In this day of large tonnages and efficient machinery it is interesting to visit the lead region of Washington county, Missouri, where mining methods of a century ago prevail.

This is not only one of the oldest mining regions in the United States, for Renault and his French followers began work here in 1720, but for a number of years at least, it was the most important mining district in the country. Washington county's production to date of lead ore, and a little zinc ore, amounts to \$6,800,000. This production has varied greatly from year to year, increasing with new discoveries, high war-prices, droughts, and crop failures.

Washington county is situated in south-east Missouri from five to thirty miles west of the disseminated-lead belt. Topographically, the region is a plateau, the flat rocks of which have been trenched by numerous streams to a maximum depth of 500 ft. Certain distinct hills are composed of pre-Cambrian granite and rhyolite.

The following rocks, named from youngest to oldest, and all of Cambrian age, according to E. R. Buckley,* rest upon the rhyolite and granite:

	Thickness
Potosi formation	400 ft. or more
Doe River limestone	47 " "
Derby formation	39 " "
Davis shale	169 " "
Bonnetterre limestone	366 " "
Lamotte sandstone	250 " "
Granite or rhyolite basement	

All of these formations at various places are in unconformable contact with the granite and rhyolite. The sedimentary rocks are flat or gently flexed, and normal faults of considerable displacement are common.

Practically all of the Washington County lead has come from the Potosi limestone, although a little has been obtained from the other sedimentary rocks. The main ore-horizon of the Potosi is from 600 to 1000 ft. above that of the disseminated lead which has made south-east Missouri the premier lead district of the United States. It is probable that no particular stratum in the Potosi is throughout the whole county especially favorable to mineralization. Locally certain more soluble beds are so, but the orebodies are primarily related to the present surface and only secondarily to the more soluble beds of limestone.

The map shows that the county contains a vast number of small lead mines, a 'digging' producing 50 tons of ore being considered locally of importance. Some of the larger mines, or groups of mines, have, however, produced from \$1,000,000 to \$1,500,000. The mines are

particularly abundant around the villages of Potosi, Palmer, and Richwoods, the Potosi group having produced perhaps 55% of the total output, and Palmer perhaps 35%. The accompanying map does not show, by any means, all of the diggings in the district.

The orebodies are either residual or lode, the former, of course, being derived from the latter. The lodes can be classified into crevice deposits, pipe-veins, and breccia-fillings. The crevice deposit is a vertical tabular body of ore, the 'gash-vein' of Whitney. In depth these orebodies pinch, as the joint along which disintegration had occurred tightens. In instances cross-veinlets extend

MAP OF WASHINGTON COUNTY, MISSOURI

from the main crevice at right angles following a secondary joint. East-west and north-south crevices are most common. These deposits are occasionally in sets, the ore having been deposited in several parallel joints.

The pipe-veins are semi-cylindrical orebodies lying in a horizontal plane. They are from three to eight feet wide and average six inches thick. There is usually one main 'pipe' of ore that fills a semi-cylindrical hole in the limestone caused by solution of a favorable-limestone bed along a joint. Many minor pipes lead off from the main one, following joints, at, or nearly at, a right angle to

*E. R. Buckley, Mo. Bur. of Mines & Geol., Vol. IX, pt. II, 1908, p. 19.

the main pipe. Systems of pipe-veins may occur at several horizons in the Potosi formation, one above the other. Excellent examples are the Flint Hill and Parole diggings, and a map of the latter by H. A. Wheeler, of St. Louis, forms plate 119, in Part II, of Buckley's report, previously cited. In some instances pipe-veins have been followed horizontally to points 150 ft. below the surface, constituting the deepest workings in the district. The orebodies of the third type are vertical tabular masses of ore cementing either fault or solution breccias.

The residual deposits, or 'clay-workings,' as they are known in the district, are the orebodies just described, from which the enclosing rocks have been more or less completely dissolved by surface waters. The galena of the crevice deposits still frequently remains in a vertical position. Immediately above the bedrock there is a considerable mechanical concentration of lead ore. If solution has been incomplete, the so-called 'tumbling rock' formation of the native miners is found, in which the lead ore occurs between, although usually detached from, boulders of flint or limestone. In the early days some placer galena was recovered from the stream-beds.

The lead deposits are particularly common on hill-slopes, from which, however, they may extend back underneath the plateau.

The original sulphides include galena, zinc-blende, pyrite, and marcasite; also a little chalcopyrite. Galena cubes are usually rounded through solution and are partly altered to cerussite, which in some instances is white and crystallized, and in others is a gray powder. In many mining districts the value of zinc-carbonate has long remained unrecognized, but James T. Hodges states that in this locality cerussite was for many years thrown on the dump and that only in the 'forties were the dumps hand-picked for it. Anglesite is probably associated. The galena usually occurs as small cubes disseminated in 'chalk-tuff,' although in instances it is found in 'ball-tuff.' In the old days lead in large cubes was found in some cavities. Zinc-blende alters to smithsonite, and pyrite or marcasite to limonite, and rarely to hematite. Chalcopyrite alters to chalcocite and malachite. Barite is the common gangue-mineral, and this occurs either as 'ball-tuff,' a conical aggregate of large tabular crystals, or as 'chalk-tuff,' a finely crystalline aggregate. Gypsum (the 'isinglass' of the miners) appears to occur only with residual lead, and doubtless formed comparatively recently in the clay. Calcite ('glass tuff'), is by no means uncommon in the district, but usually is not closely associated with ore. A substance frequently accompanying the ore is the 'yellow paint' of the miners, a heavily iron-stained, rather hard, yellow clay.

The sulphides and original gangue-minerals were usually deposited in cavities, although in certain of the rare fault-breccia deposits the sulphides, in part, replace limestone. Smithsonite, a secondary mineral, also replaces, to a certain extent, limestone along fractures. The primary minerals are usually rather well crustified, and from the limestone, chert, or crystalline quartz walls

outward, the ordinary order is: iron pyrite, or marcasite, zinc-blende, and barite with galena. The reverse sequence, indicating however the same order of deposition, is found on some of the stalactites. Sometimes, next the rock, partly formed pyrite or marcasite crystals and aggregates have barite between them, and the galena crystals are incomplete and enclose barite. Further, in rare instances, a pyrite crystal is isolated in the barite itself, indicating that the depositing waters were not always as distinct as casual observation would indicate. Certain members of the series may be absent, as at Madden Hill, near Palmer, where galena is plastered directly on chert. Of the two types of barite, 'ball-tuff' is older and is sometimes covered by a coating of 'chalk-tuff,' the two contacting sharply. Due to the predominance of one mineral over others, some prospects are lead mines, others zinc prospects, and still others, barite producers.

That these lead orebodies, with the possible exception of some of the breccia deposits, were deposited by descending meteoric waters is indicated by the fact that at comparatively shallow depths they pinch out. Stalactitic masses of altered iron sulphide, galena, and 'chalk-tuff' are common on the dumps, and old miners report that all were found pendant from the roofs of openings. The source of the lead is unknown, although it was originally doubtless disseminated in the Potosi or some overlying formation. That the sulphides and barite are much younger than the flint, and the crystalline quartz covering it, is indicated by the crustification mentioned above, and also by the fact that the ore occurs in fractures in the flint and quartz. As to age, the orebodies are believed to be geologically young, and for the most part, to be contemporaneous with the present, or a comparatively recent, topographic cycle.

The miners around Palmer are Americans, the grandsons or great-grandsons of Kentucky or Tennessee mountaineers. Those at Old Mines north of Potosi are descendants of French miners, some of whom arrived in Missouri about 1720. Among the older men French is still frequently spoken. For at least three generations both Americans and French have been miners, and the mining methods are to a considerable extent those evolved in Missouri. A few, however, trained in mining, were among the early French settlers. Sixty years or so ago a number of Cornishmen emigrated to the district, and a few miners have drifted in from other regions. Prior to the Civil War certain 'diggings' were worked by negro slaves, some being continuously employed in mining, others being sent into the district in winter, after the crops were harvested. At the present time the descendants of Kentucky and Tennessee mountaineers, Cornish miners, French adventurers, and former negro slaves work amicably in the same diggings.

The wants of these people are few, and the standard of living not high, from \$1 to \$1.25 per day being considered a fair wage. While many have drifted to the large mines of St. Francois county, others prefer to be their own masters, and will inform you gravely that their

earnings in the shallow diggings average better than the \$3 or \$4 obtainable in the disseminated-lead mines. Of course some few, when in bonanza, for a time do well, but as an average their earnings are much less than \$1 per day. However, the pleasure of being your own master has distinct advantages, and days in bonanza when \$5 or \$6 or even \$10 were made, are much less easy to forget and more pleasant to remember than days of disappointment. The work-day is a short one, and it is rarely that both partners, two being the common number, arrive at the shaft before 9 o'clock, and at least one is usually gone by 3 o'clock in the afternoon. No work is done on Sunday, and on Saturday the day is spent at the local store discussing politics and the latest lead strike. Many reasons are sufficient to stop work: too much wet weather; too dry a season; too cold weather; or too good a chance to work for a short time for day's wages. Perhaps during the year 175 to 200 rather short days' work is the average. If one has luck it is the custom to stop work until the money is eaten up, then to run an account at the village store, if possible, until one again gets into bonanza. Possibly if longer hours were consistently observed, from \$1.50 to \$2 a day might be made by the more skillful miners.

Mining is done under a leasing system, the payment being variously arranged. In many instances the company owning the land demands a royalty that may vary from 10 to 20% of the lead ore mined, and 15% of the zinc ore; or the miners are required to sell their product to the owners of the diggings at a price that nets on its re-sale a handsome profit on the St. Louis lead price. In the more prosperous days of the diggings a company weigher with bar-scales and wagon, went daily from one 'digging' to another, weighing the day's product and giving a ticket accepted at the company store in goods or money. The lead ore was hauled to one of the small furnaces then so common in this district. At the present day all country storekeepers in the vicinity buy lead and zinc ore at a price considerably higher than the company pays, and either take out the royalty to be later paid to the property owner, or pay all to the miner, who is expected to settle with the land-owner. Rarely, if ever, does the owner of the property fail to receive his royalty. In the boom days the discoverer of a new 'digging' was permitted to stake off a claim twice the size of that allotted to later comers. The discoverer's claim might be 100 to 200 ft. square. The size of the plot also increased with greater depth to the ore-horizon, and claims in which the ore occurred in rock were perhaps five times the size of those in clay.

In prospecting, the well-known 'mineral blossom' (flint covered by transparent quartz crystals) so characteristic of the Potosi limestone, showed the old miner he was on the lead-bearing formation. If this was not present, there was little use of further search. He then sized up the topography, choosing some hill-slope that suited his idea of a promising mineral district. The streams were carefully searched for galena pebbles, and if found, they were followed up-stream until they dis-

appeared, at which point the hillside was trenched. 'Chalk-tiff' was also considered a good indicator, particularly if it contained cubic cavities, indicating that once galena had been a constituent thereof, as were yellow clay ('yellow paint') and limonitic iron ore. 'Ball-tiff' was believed to indicate a pinching out of the deposit, or barren country. A summary of the conditions favored by the old miners 75 years ago, is given by James T. Hodge.†

"Throughout the several counties which are occupied with this formation (limestone), the miner recognizes a proximity to the fissures by the abundance of the peculiar red clay of the hematite iron ore, and of the botryoidal and mammillary masses of quartz rock, and the exact position of the fissure itself is often indicated to his experienced eye by a slight sinking of surface and an east and west or north and south line of brushes or plants which have deep sinking roots and choose a situation where they can send them deep down into the clay. Still these guides are not always sure, for men used to the business often spend a year or more in 'prospecting,' that is, in sinking experimental shafts or following a fissure in hopes of its yielding a rich return of ore, and all without success. But by continuing their work, if their means allow of it, they seldom fail of finally striking a 'lead,' the sale or working of which repays them for all of their labor."

The residual or 'clay' workings are mined by sinking round pits four feet in diameter to bedrock, where the lead ore is notably concentrated. At the ore-horizon the clay is undercut, and the ore removed to a safe distance from the pit. When the pit becomes dangerous, another hole is begun, perhaps 15 ft. from the centre of the first pit; the process is continued until an area sometimes 40 to 100 acres is riddled. The tools used are a short-handled shovel, and pick; when the hole is over eight feet deep a hand-windlass and bucket are added. Horse-whims, and even small steam-hoists, have been introduced on a few of the deeper workings. The ladder in the deeper holes usually consists of a tree on which a few stumps of branches have been left. Pumps are practically unknown, and if water (usually encountered at a depth of from 70 to 100 ft.) interferes with mining, work is usually stopped. The deeper shafts (the deepest around Palmer being about 150 ft.) are square, about four feet in the clear, and in instances timbered in the clay with small pine-lagging. Work usually stops at solid rock and even in it the amount of dynamite used is small, as the partly decomposed limestone usually crumbles to a lime-sand upon being struck. It was but 35 years ago that black powder was discarded, and rumor has it that at Flint Hill, some 70 years ago, the good old Roman method of building a fire on the rock and then throwing cold water on the heated stone was practised. As one of the miners remarked: "That seems like a right hard way to mine, don't it?" From the bottom of shafts, drifts usually 4 by 4 ft. in the clear are run. Two men will sink a round shaft in clay 10 to 12 ft. per day to

†*Am. Jour. of Sci.*, Vol. 43, 1st series, 1843, p. 57.

depths of 25 to 40 ft. and will sink and crib a square shaft 5 to 6 ft. per day; and drive 8 to 10 ft. per day. In the rock they sink from $1\frac{1}{2}$ to 1 ft. per day. The corresponding costs per foot are about 17 to 20c., 24 to 40c., 20 to 25c., and \$2.50 to \$5. No figure can be given of the cost of one ton of mined and cobbled galena, but in instances it is as low as \$5 to \$15.

The ore as it leaves the mines is a mixture of galena and barite. The coarser ore is cobbled by a half-pound hammer with a horizontally set chisel-point, called a 'pickawee,' a corruption of pick-a-way. A light sharp tap with this usually separates the two minerals. The finer mixtures are thrown on the fire where the 'ball-tiff' (barite) breaks down into sand and the galena cubes are easily picked out. The 'chalk-tiff' needs a hotter fire and is less successfully treated in this manner.

Most of the dumps have by now been 'scraped' many times; that is, their surface has been carefully raked over to find any galena left by the earlier miners. The dumps, however, keep some of the more industrious boys of the district in modest spending money.

Washington county produces about one-half the barite of the United States, the centre of activity being Potosi. It has been stated that barite is the common gangue of the shallow lead deposits and it also occurs in deposits by itself with little or no lead. Barite is rarely followed into the hard rocks, as, on account of its low value, it is only profitably mined in residual clay, where, against bedrock, due to its insoluble nature, its concentration is intensified. It is mined, as is the residual lead, in the shallow diggings already described. The barite with the adhering red clay is spread out to dry and is then placed in a sort of cradle—a box mounted on rockers, the bottom of which consists of an iron plate with half-inch holes punched in it. Violent rocking jars off the clay, which drops through the holes in the cradle. The buyers usually pay for the 'tiff' at the various diggings and haul it to the railroad. As the price obtained is low, barite diggings are rarely situated more than six miles from the railroad.

DIATOMACEOUS EARTH, which is made up of remains of minute aquatic animals, is a light earthy material resembling chalk or clay. The hardness, the minute size, and the angular shape of its grains make it an excellent metal-polishing agent, and heretofore it has been largely used as an abrasive in the form of polishing powders and scouring-soaps. Of late, however, according to the U. S. Geological Survey, the uses of the mineral have been considerably extended. It is used by sugar refiners for filtering or clarifying; as an insulating packing-material for safes, steam pipes, and boilers; and as a fire-proof building-material. In the United States it is used in the manufacture of records for talking machines. In Europe it has been used in preparing artificial fertilizers and in the manufacture of water glass, cements, artificial stone, paper, sealing wax, fire-works, papier mâché, and other articles. A total of 4593 tons of diatomaceous earth was produced and sold in the United States in 1915.

Types of Asbestos

*Three types of asbestos fibre are recognized—cross-fibre, slip-fibre and mass-fibre. Cross-fibre (chrysotile) asbestos occurs in veins with the fibres extending transverse to the strike of the vein. Usually the fibres are approximately perpendicular to the inclosing walls, frequently they are more or less oblique and occasionally they are curved or abruptly bent. Slip-fibre is found along fault planes, often accompanied by slickensides, and the direction of the parallel fibres records the direction of displacement. The amount of displacement is usually small. Slip-fibre asbestos is commonly distributed in thin layers that are not as a rule continuous for any considerable distance, but occasionally it is found in masses a foot or more in thickness. All gradations are to be found between the cross-fibre and slip-fibre types. Mass-fibre asbestos occurs in fibrous bundles or groups varying in size and orientation. The fibres may be parallel but are usually divergent and often radiating. In the type occurrence at Sall Mountain, Georgia, mass-fibre asbestos makes up practically the entire rock mass. Anthophyllite has been reported as occurring in all three ways, and it is the only variety of asbestos known to occur as mass-fibre. The asbestiform varieties of tremolite and actinolite are practically limited to the slip-fibre type.

Chrysotile easily withstands temperatures of 2000° to 3000° F., while with some varieties a temperature of 5000° F., produces no visible effect. At red heat it gives up water and becomes brittle. Anthophyllite under the same conditions remains practically unaltered. Tremolite and actinolite fuse at somewhat lower temperatures, while crocidolite fuses so easily that it is useless for many purposes where asbestos is commonly employed.

Chrysotile is readily attacked by relatively weak acids; being decomposed with the separation of silica; the amphibole varieties, especially tremolite and anthophyllite, are very resistant even when subjected to the action of concentrated acids.

MINERS operating hydraulic placer mines, and those operating in open-cuts commonly break up boulders and large masses of rock by the method known as bulldozing, but actual experience has shown that it is far less expensive in most cases to shatter these boulders and large rocks by block-holing with the hammer-drill. To bulldoze effectively a big rock requires from 4 to 10 sticks of dynamite, whereas the same work can be accomplished with one or two sticks if a hole or two be first drilled in the rock with a hammer-drill. At the mine of the Placer Gold Mines Company, near Atlin, B. C., the cost of breaking up boulders in 1915 was reduced about \$1200 over the cost during the season of 1914, an amount almost equal to the expense of a Sullivan compressor and two 40-lb. Sullivan drills installed expressly for the purpose of block-holing boulders.

*Abstract from Trans. A. I. M. E., New York meeting, February 1917.

Black Sand of the Pacific Coast

By Herbert Lang

The problem of the black sand has been with us for a long time and has been attacked by many investigators, usually with poor results. The work done has been mainly of a desultory nature, due, no doubt, to the scattered state of the deposits, which are not, as a rule, either large enough or regular enough in tenor to warrant large-scale operations. However, conditions now are such as to favor further examination and perhaps development, among these conditions being the unexampled rise in the price of platinum, a metal that is not infrequently found in the black sand. Possibly some of our idle prospectors, whose future is giving their friends so much concern, may find it to their interest to turn their steps that way, the more so that the examination of this class of mineral deposit involves comparatively little expense or trouble.

At the outset we have to bear in mind the differences between the two great classes of such deposits, namely, the beach or sea sand, and the river or stream sand. The latter is present in variable quantity in all placers. The first noticeable difference is the great diversity in size of grain—the sea sand not being mixed or associated with the coarse gravel and boulders characteristic of stream placers. On the other hand it contains much finely pulverized material scarcely coarser than wheat-flour. While black sand, properly so-called, is distributed through all placers, and is found in large quantities in some, as a rule it occurs only in small patches and never in amount sufficient to necessitate special metallurgical arrangements for its treatment. The old-fashioned methods of washing, applicable to placer work in general, have been found equally adapted to treat the comparatively restricted collections of black sand. Along the beaches, however, the black sand is found at times in such great quantity as to justify improved methods of treatment. It would only be advisable to make such improvements in the event of finding large deposits, growing larger by constant addition from the original source.

Beach sand is generally deposited free from the boulders with which it must have been at one time associated, and forms a comparatively homogeneous mass, the particles of which do not vary widely in size. In samples that I have screened, and that have been derived from widely separated beaches, the size of grain varies from 30 to 200-mesh, although the dry sand yields occasionally a small amount of even finer dust. The sand, of course, is made up of hard particles of the rocks from which it was derived by erosion, and we find in it quartz, garnet, olivine, zircon, and other silicates, together with magnetite, chromite, titaniferous iron and hematite, along with a very little gold, and once in a while a little platinum. One ought to emphasize the scarcity of the gold and platinum, because the impression has prevailed for a

long while that this sand, or at least a considerable part of it, is rich in gold, but which, owing to some fault of Nature, cannot be successfully recovered. Nothing of the sort is true; for while there are occasionally found some isolated areas of a few square feet, or more likely a few ounces of material that will yield a respectable assay, the average is very poor indeed, and I question if the beaches, even those upon which work has been long carried on, will average more than 10, or at most, 15 cents per ton in gold. Averages, of course, are what we are after in an inquiry like this, and time must not be wasted in chasing sporadic occurrences of rich material that may be reported.

The origin of the beach sand has been much discussed, some observers arguing that because of the presence of the gold it must have had a different origin from ordinary sand, and that the precious metal must have been brought to the ocean by rivers eroding distant auriferous formations. Others, with more reason, maintain that they were formed in the usual manner, by the erosion of the adjacent country, and that the sand is merely the more resisting portion of the rocks. The association of gold proves nothing one way or another, excepting that its form, which is peculiarly thin and flat, militates against its origin in ordinary quartz veins. It doubtless came, like the other constituents of the sand, from the eroded rocks near-by. Platinum is known to originate in basic rocks containing abundance of pyroxene and peridotite, and accordingly it is not surprising to find that metal most abundant along shores abounding in serpentine, a derivative of those rocks, as along the coast of southern Oregon and northern California.

The casual wayfarer sees nothing in these beaches that he has not seen in those of other sea-shores, neither as to their extent or their character. Even on closer examination they appear the same. One notices here and there small areas of darker sand, indicating a concentration of some of the constituents in a confined space; but this is not uncommon on any beach. Magnetic iron, which characterizes certain beaches, is found everywhere in natural sand, and even in fine soils and silts. Nevertheless, it is the magnetite, with some other associated heavy minerals, that is the surest indication of precious metal in beach sand.

Nature, in wearing down the rocks and pulverizing them into sand, performed, as has been frequently remarked, a process of concentration affording a source of wealth, somewhat ambiguous, some will say, but still a source of wealth. Her method has been likened to that employed by man in the milling and dressing of metallic ores. But the parallel is not exact. Nature, indeed, did

the crushing, with the production of oversize, sand, and, doubtless of much slime, which last has disappeared, having been spread on the floor of the ocean, to help in building new continents. She laid down the sand, however, where it remains accessible in enormous amount; but forgot to size it. It is much as if we were to attempt concentration without putting screens into our mill. We know what equal-falling grains are, and we know that we may have a small grain or particle of gold, a larger particle of magnetic iron, and a still larger particle of quartz that will fall through or be driven about by currents of water and land together every time they are moved. This is characteristic of sea-beach sand universally—it is composed of masses of equal-falling grains of a great many minerals varying much in density, but all moved by the waves in the same way. While the waves run the grinding continues, grains of the sand are worn smaller; are sorted and removed, and new associations are formed. In some way, very hard to understand, the grains of black sand are sometimes brought together in large quantity, and doubtless the white ones are also; but no one would notice that. Why this happens I do not know, nor have I even seen an explanation. We cannot imagine that they were always thus together. Whatever be the reason, the waves sometimes make collections of dark grains, segregating them by themselves for a time, only to disperse the collection when the next storm comes. Along the bluffs that front the northern coast you may see as many as twenty layers of black sand interstratified with as many white or gray. But these layers are the edges of short lenses, which thin out and disappear within a few feet, to be succeeded by others. Most of the black layers are quite thin—an inch or two, only, in thickness. We find the same condition if we sink pits or bore-holes in the beach to test the deposit. We may cut a hundred different layers of varying quality in sinking 50 ft., especially as regards the gold content. Variability in composition indicates a similar variation in gold content; whence we may find comparatively rich portions, carrying perhaps 50 cents worth of gold per ton, lying within a few feet of totally barren white sand, as one would infer from what has been already said, is more likely than not to be the poorest of all.

Gold is found as a rule associated with the denser and darker minerals of the sand, such as magnetite, ilmenite, hematite, and chromite. As between two samples of sand, the darker will almost invariably be the richer in gold. Furthermore, in a given sample, there is a peculiar relation in size of particles, the darker and heavier being likewise the smaller. This peculiarity arises from Nature's omission to screen the sand—a vital proceeding in wet concentration. The natural and obvious thing to do, then, is to perform this operation, instead of attempting to extract the gold from the mass of equal falling particles surrounding it. Screening of the sand is effective in collecting all the gold particles, and the whole or the major part of the dark minerals, in a much diminished bulk. I have obtained interesting results by screening many samples of such sand, varying widely in

composition, from material containing but few dark particles, to aggregates made up almost wholly of heavy minerals. By adapting the size of screen-mesh to that of the sand, we may make as many separations as we like. A typical sand may contain particles ranging from 30-mesh down to 150 or finer, and in such case the whole of the magnetite, the ilmenite, etc., will probably pass the 80-screen, and the most of it the 100. Hence an ordinary auriferous sand, containing, say, 15% of heavy minerals, may easily be concentrated so that those minerals along with the gold will go into one-fifth of the original bulk. This fact is of great importance in a rational scheme of metallurgy. It will be noticed that the grains staying on the coarser screens are exclusively white or gray, consisting of quartz and the light-colored silicates, while, as finer screens are employed the product passing through is darker and darker. The gold, being in a fine state of subdivision, stays with the finer sand, and at the end we have a comparatively small quantity of richer material to treat. This simple method of concentration, which after all only supplements Nature's operation, would, of course, be effective only on sand containing a comparatively large proportion of white grains; for if the deposit consisted of magnetite alone there probably would be no concentration by the screening method, since the particles of any single mineral collected in one spot are apt to be nearly of the same size. Some experience in the actual washing of the sand is necessary to enable one to appreciate why the simple sluicing of the natural sand is such an ineffectual operation when it is designed to catch the gold. It is evident that material repeatedly concentrated by Nature and delivered to hand in assorted and equal-falling grains cannot be separated effectively by a repetition of the process. What Nature has done on a great scale is feebly imitated by man, with his puerile rockers, long-toms, and sluices, but to little purpose indeed. It is also evident that in view of the poverty of the sand, that its treatment, profitably, must be on a far greater scale than hitherto known, and with better directed and more comprehensive processes.

Although the impression has got abroad that the gold in black, and especially of beach, sand is difficult to treat metallurgically, the contrary is the case except as regards amalgamation. A great deal has been said, which it is not necessary here to repeat, about the existence of a "coating" on the gold, which renders it "rebellious," or "refractory," or something, so that mercury, and perhaps chemicals generally, have little effect. But the fact is, the gold of black sand is perfectly amenable to cyanide and to chlorine, and furthermore, the ordinary constituents accompanying it are perfectly inert toward those reagents. Should sand be found in quantity and of a quality to warrant the installation of a plant, using either cyanidation or chlorination, there would be not the slightest difficulty in recovering the gold profitably. Smelting has been suggested as a promising means of beneficiating the sand, especially of the heavier kinds, doubtless with the idea in mind of using it as profitable

flux, to take the place of basic material. But this suggestion must have originated under the belief that the black particles are exclusively magnetite. Were it mainly so there is no question that it would serve as a flux, and in case the gold tenor were sufficient, it could be employed with profit. Analysis, however, shows the presence of too many deleterious minerals, including the most of those above named. No one would desire to add either titaniferous iron or chromite to his smelting mixture, for reasons known to every metallurgist, and it goes without saying that silica and the silicates would prove, though for a different reason, an undesirable addition to the furnace burden.

Proposals have been made from time to time to employ the sand as an ore of iron, from which to manufacture that metal, and especially steel. The suggestion could hardly have been made with a knowledge of their actual composition, however, since it may be easily understood that the presence of chromite and ilmenite, would effectually bar the success of such a proceeding. It is only necessary to use a magnet to discover that in almost every case a large number of the black particles are not magnetite, while a few blowpipe tests will reveal the real character of the non-magnetic portion. Analyses of many samples of black sand may be found in 'Mineral Resources of the United States' for 1905. The data published are valuable, but like much that is printed by the Government bureaus are ill digested, and are not brought into correlation with actual mining.

The examination of beach-sand deposits is generally confined to panning occasional samples from the surface; it is only exceptionally that anyone takes the trouble to drill the deposit systematically after the manner of those who investigate dredging ground. One deposit of 200 acres of sand on the Oregon coast was carefully bored, however, but with disappointing results; as instead of a content of \$4 per yard, as was alleged, the highest assay was but 60 cents per yard, and many assays showed no trace of gold. As the gold is entirely free, its connection with the associated minerals being wholly physical, the pan or batea serves perfectly well in skilled hands for obtaining an adequate idea of the quality of the material. Skill, however, is necessary, since the gold has a strong tendency to float off. The panner finds it necessary to wet the sand carefully in his implement first, and then to keep the pan and its contents covered with water at all stages of the operation. So marked is the tendency of the gold to float when dry that at one time I thought it feasible to employ this tendency as an aid in concentration. If the dried material is thrown upon water, the gold, and with it considerable dust, floats and can be gathered up by suitable means, forming an enriched product, which might be called a 'concentrate.' Whether this principle could be reduced to practice remains to be seen. If by this means or by screening, or by a combination of them, there could be secured a product sufficiently rich to pay for cyaniding there would be a chance for establishing an important industry. Others have suggested the use of magnetic concentration to free the gold-

bearing material from at least one of its constituents, preparatory to the application of some process of gold extraction; but this would not seem to promise much in view of the general composition of the sand.

I conclude therefore:

1. While isolated tracts of small extent are comparatively rich, running in some cases, as reported, as much as two or three dollars per ton, most of the deposits carry but a few cents in gold per ton.

2. The sand must prove valueless for steel-making, unless, which is most improbable, masses of pure or nearly pure magnetite shall be found, large enough to be worked commercially, and in favorable localities. The fine-grained condition of the sand would be an obstacle to its industrial utilization for this purpose.

3. Although a few miners are even now making a precarious living by washing beach sand along the northern coast, where it is richest, no regular and important industry has been, or will be, built upon the crude methods of sluicing there practised.

4. A rational scheme for their working must involve some form of concentration, to be followed by the application of some process more effective than amalgamation.

Flotation and Dividend Payments

As is well known, the Minerals Separation company has a suit against J. M. Hyde, really the Butte & Superior Mining Co., in the United States Supreme Court. This is an appeal from a lower Court in the case of alleged infringement of M. S. flotation patents, and a decision is expected at an early date. At Butte, last week, Minerals Separation made an effort to prevent, through injunction proceedings in the Federal District Court, before Judge Bourquin, further payment of dividends by the Butte & Superior company and the proposed consolidation with the American Zinc, Lead & Smelting Co. It is probable that a bond of sufficient sum to insure Minerals Separation against any loss in case it wins its present suit with Butte & Superior will be asked by the Court. The Butte & Superior company denied the right of Minerals Separation to ask for an increased bond, now \$75,000, but maintained that the latter company was not entitled to any bond to secure possible judgment in view of present status of the case.

The Judge said the whole question seemed to revolve around whether or not a bond should be required after the Circuit Court of Appeals had reversed his decision in the Hyde case, which found that oil flotation is an infringement of the M. S. patent. In asking an increase in the bond, Minerals Separation stated that since the first decision in the case, dividends aggregating \$13,098,288 have been distributed to stockholders of Butte & Superior. Official reports filed in Court showed that flotation has netted Butte & Superior over \$15,000,000. Butte & Superior denied that it was to dispose of its properties to American Zinc.

Mining in Nevada

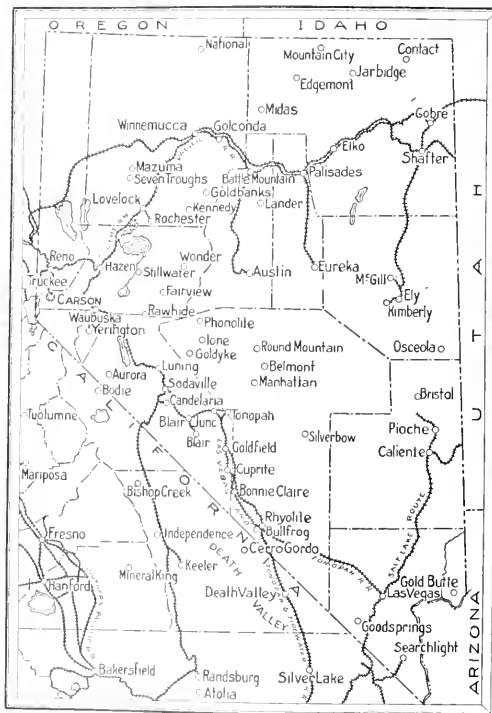

By Al H. Martin

Tonopah has settled down to a fairly steady output of approximately 10,000 tons of ore per week, averaging \$19 per ton. Of this, 7200 tons is from the Belmont, Extension, and Tonopah Mining properties, the remainder from the Jim Butler, West End, Halifax, Rescue-Enla, North Star, and leases on the Montana, MacNamara, and one or two others. The Extension continues to yield the most consistent grade of ore. Sinking of the Victor shaft of the Extension has advanced to a depth of 1720 ft., fair progress being made, although heavy ground was encountered recently. On the 1540-ft. level stoping is going forward on the Murray and North Merger veins, and considerable exploration is being done west of the shaft. On the 1350 and 1410-ft. levels the Murray, North Merger, and O. K. veins continue to develop splendidly. At 1440 ft. the Murray has widened to 6 ft., being the same width as at 1350 ft. On this level the Merger vein is 8 ft. wide, and the O. K. is yielding good ore across a width of 4 ft. From 950 to 1350 ft. extensive work is proceeding on wide faces of milling ore. As soon as the 1850-ft. point is reached cross-cuts will be extended to cut the Murray and other veins to the west. The Belmont company is exploring vigorously with diamond-drills large areas about a mile east of the Belmont mine. This work is being done in virgin ground, and is attracting considerable interest. Net earnings of the company for the first nine months of 1916 amounted to \$929,345, May being the largest month with \$126,263. Work is proceeding on all levels from 600 to 1500 ft. A 4-ft. shoot of promising ore has been opened in the Monarch-Pittsburg, and a 66-ton test shipment made to the West End mill. The discovery was made in raise 1925 from drift No. 1003, and the shoot has been followed for 30 ft. An intermediate west drift has been started at the point of discovery to prospect the formation more thoroughly.

Although reported many times during the past two years there is a strong probability that the Thompson smelter of the Mason Valley Mines Co. will be blown-in within 70 days. Repairs to the plant have been made, and work resumed on a small scale in the mines. It is announced that the 10-ton leaching-plant, operated several months as an experiment, has proved successful and will be enlarged. Sulphuric acid is used as a solvent, and the process is stated to be applicable to either carbonate or well-roasted sulphide ores. Credit for success of the experiments is due G. A. Bragg and E. R. Weidlein. It is understood that the smelter will treat ore from the Bluestone mine, near Yerington, and several small producers in the vicinity of Luning, Mina, Reservation, and other centres, where considerable gold, silver, lead, and copper ore is available. Shipments will also probably be received from the Gray Eagle copper mine, near Happy Camp, California, recently acquired by the Mason Valley company. The mineral holdings of the company consist of 150 acres 1½ miles west of Mason, together with the 1320-acre smelter site and 320 acres of agricultural land. The ore occurs as a contact deposit in limestone and andesite, and has been opened to a depth of 550 ft. Surface ore consists mainly of malachite, but at a depth of 100 ft. massive pyrite containing chalcopirite forms the valuable mineral. The main orebody averages 30 ft. in width, with ore of medium grade.

At Goldfield the exploration of promising territory in the Silver Pick and Jumbo Junior claims considerable interest. The attempt of the Florence Goldfield company to treat profitably its oxidized and low grade gold copper sulphide ore with flotation resulted unfavorably, and the mine and plant have

been closed-down. Sampling of the orebodies proved unreliable, because of constantly varying metal-content, and in many instances the mill-feed was found unprofitable, although sampling indicated the reverse. The company is understood to be contemplating dewatering the 1100-ft. shaft, which is filled with water to the 650-ft. point, with a view to exploration of promising sulphide deposits in the deeper levels. It is also possible that this work may be undertaken from the

MAP OF NEVADA.

deep levels of the adjoining Atlanta mine. Upper workings may be leased. As the company has no facilities for treatment of its oxidized ore, this material will be saved for milling until cyanide equipment can be secured. A large station has been cut just above the 1100-ft. level of the Silver Pick shaft, and a west cross-cut started to intersect the ore-shoots found by the Calyx drill. While sinking a sump, quartz assaying better than at the station was cut, and the shaft will be continued until the alaskite has been penetrated. Seams of ore are exposed, and the excessive faulting of the formation encourages the belief that profitable ore-deposits may be discovered in the alaskite. The Calyx drill is boring a third hole several hundred feet west of the main workings. The new raise from the 880-ft. workings in the Jumbo Junior has intersected fair ore near the Kewanas line, indicating that the vein extends into Kewanas ground. The winze on the vein, near the

Jumbo Extension line, has been discontinued temporarily, and arrangements made to prospect the deposit from the deeper levels of the Jumbo Extension. Driving at this point indicates that the work has been on top of the deposit, and hopes are held for the uncovering of an important body in the shale-lalite contact. The work is going on a short distance north-east of the Velvet claim of the Jumbo Extension.

The C. E. Jury Syndicate, of Toronto, Canada, is preparing to prospect actively the West Comstock district, near Virginia City, recently taken under bond for a reported consideration of \$450,000. The chief engineer, Charles Baycroft, is on the ground arranging for extensive exploration with diamond-drills. It is planned to prospect thoroughly the orebodies to a depth of 1500 ft. The district contains the Bargo, T. & E. Fluck & Mahoney, and other promising mines, and the bond and lease is for two years. The deal was made by W. B. Thomas, long connected with mining in the district, formerly known as the Jumbo field.

Manhattan again shows a disposition to become an important gold producer. Recent work in the White Caps, Big Pine, Big Four, and other mines has been encouraging, particularly in the White Caps. At this property deepening of the 310-ft. shaft to the 435-ft. point is proceeding, and as soon as the objective is gained a series of drifts will be extended to open the shoots disclosed east and west of the 310-ft. workings. Foundations for the roasting-plant are being installed, and the mill will be moved to a site nearer the mine.

Officials of the Salt Lake Route recently inspected the line between Jean and Goodsprings with a view to widening it between these two points by means of a third rail, and extension of the road to supply the mines being developed west of the Columbia Mountain range. Several good properties have been opened in this region, and are in need of transportation facilities. The Akron and Bill Nye properties have been merged into the Goodsprings Bill Nye Mining Co., and arrangements made for an enlarged yield. The Bill Nye has been shipping zinc-lead ore for several months. On the Akron, ore giving high assays in silver and zinc has been opened.

As has been mentioned before, Utah people are to erect a sampling-plant at Jean to handle Goodsprings ore.

Shipments of high-grade copper ore, also containing platinum and gold, are going out from the Boss mine; a recent consignment is reported to have been one of the richest ever shipped. Material and equipment for the new mill are arriving, and the management expects to have the plant in operation about the middle of January. High-grade copper-gold-platinum ore is being shipped from the Oro Amigo, where a deposit assaying 10 to 45% copper was recently opened. On the Milford-Addison, controlled by the Goodsprings Mining Co., a 4 ft. deposit of practically pure sodium chloride was discovered last week. Some of the salt will be used in the new chlorination plant of the Boss company, and shipments made to Los Angeles.

The new camp of Wallace, discovered a month ago by Robert Wallace at a point 12 miles from Winnemucca in the Silver range, is attracting some attention. The Whitaker-Newlands lease has opened a 12-in. shoot at a depth of 35 ft., that is claimed to assay over 800 oz. of silver per ton. On the surface James Truitt and Floyd Harman have opened a 24-in. vein for a length of 200 ft. The ore occurs in contacts of lime-diabase and porphyry-diabase. E. D. Rogers of Sulphur has leased several blocks of promising ground and is building a good camp, preliminary to extensive work. Ore containing free gold and some silver has been uncovered by Albright & Wallace, the shoot being 18 in. wide. A number of new leases have been taken in the past week, and prospecting is becoming active.

The outlook at Rochester is more favorable than for many months, largely the direct result of a more friendly spirit manifested by the leading operators. For over a year some of the foremost companies have been antagonistic toward each other, and this attitude naturally militated against develop-

ment and investment of new capital in the district. Realizing this, some of the operators recently held a conference and agreed to bury their differences. Already a change for the better is apparent. By an agreement entered into by the Rochester Merger and Nenzel Crown Point companies the former is enabled to work its Crown Point Extension claim by way of the Nenzel Crown Point laterals, and the latter company is developing its territory through the Pitt adit of the Merger. The Rochester Mines Co. is increasing its mill and completing a tramway from mine to mill. Excellent ore is showing in the northern end of the Crown Point No. 1 claim, and is being developed by way of the Causten adit. The Nevada Packard has declared its initial dividend, at the rate of 5c. per share, and is credited with an output of \$1000 per day. Good ore is reported by the Rochester United on the south end of the Sunflower claim, leased from the Rochester Merger Co.

Revival of the old centre of Eureka ranks among the most important of late mining developments in Nevada. New capital is opening the properties, many of which have lain idle for decades, and some new mines are in the making. Grossman & Koplan of San Francisco have purchased a two-thirds interest in the Republic from Mrs. May M. Des Marias, and have started work. The mine is on the west slope of Prospect mountain, and has yielded some rich ore. In the Summit, at a point approximately 2000 ft. south of the Diamond mine, a shoot of gold-silver ore has been cut near the surface. Samples assay 150 oz. silver, 50% lead, and \$10 gold per ton. A hoist has been installed on the shaft of the California, and sinking is proceeding rapidly on ore of excellent grade. From the upper workings three carloads of ore are shipped weekly. Hoisting machinery has been placed in position at the Rescue, and the old shaft deepened. Drifts will be extended to seek the veins worked on the main levels. Good ore is coming from the Diamond, Bullwhacker, Marne, and other claims. Silver-lead ore assaying \$65 per ton, with a little gold, is being opened in the Silverado property, controlled by the Summit Queen Co., under the management of Clarence Johnson. The incline shaft of the Connolly has been carried to a depth of 400 ft., and connections made with the new shaft being sunk on the Catlin group. The latter has two compartments, and a manway and will be one of the best equipped in the district.

Eldorado Canyon continues to claim attention, with a determined effort made by the mine-owners to encourage investment of outside capital. San Francisco people are displaying considerable interest, and some of the more promising groups are now controlled by residents of that city. On the Lombard claim, adjoining the Carnation, where rich ore was lately encountered, Charles Herman, M. Fisher, and James German have opened a shoot of high-grade gold-silver ore. Assays are reported to range from \$100 to \$1200 per ton. A compressor and other machinery have been installed at the Eldorado Empire, preparatory to more extensive work. Good ore is showing. The owners of the Enterprise have completed an inspection of the property with the intention of providing additional equipment. The shaft of the Cliff-Era is being rapidly completed to the 200-ft. point, despite the water. From the 200-ft. level a drift will be driven to intersect the orebody that has been traced on the surface for 4000 ft. Isaac Alcock and Frank Hoine have taken a lease on the Lucky Jim and started blocking-out of ore. A new hoist is being installed at the Skylark group, and sinking will be pressed to open fair ore exposed near surface. Several new buildings are under construction, including a hotel. Men are coming in from all parts, and numerous deals are reported to be in course of negotiation. The activity has spread to the neighboring Searchlight district, and several old properties at that point are about to be re-opened and vigorously worked, including the Duplex, Big Casino, and Searchlight. Operations have been increased at the Quartette, which recently passed into the control of New York capital.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

VICTORIA, BRITISH COLUMBIA

ESTIMATED METAL PRODUCTION FOR 1916.—REVIEW OF PROGRESS.

Estimates of the probable value of the mineral production of British Columbia, published recently, give a total of between \$15,000,000 and \$50,000,000. As the year draws to a close it seems as if there is a possibility of the lower total being reached, but little likelihood of the higher one. The provincial mineralogist, W. F. Robertson, issued the following figures as to copper production for the current calendar year: "estimated as probable, 90,000,000 lb. of copper, value \$22,500,000." This would give an increase over the value of the 1915 output of \$12,665,000. The total value of all lode metals other than copper produced in the Province last year was \$10,156,000; that of placer gold and non-metalliferous minerals was \$9,456,000. If the above quoted estimates for copper be realized and there is a 50% increase in all lode metals (which, however, seems to be unlikely for gold and lead), then, as already stated, a total value of \$45,000,000 for this year seems possible, but hardly otherwise; as it does not seem probable that non-metalliferous minerals and placer gold will together considerably exceed their total value last year. Further, the opinion may here be expressed that the quoted estimate for copper is an over-sanguine one.

Apart from great expectations relative to total value of production, there are distinctly encouraging features in the mining situation in the Province, for the total dividends paid by mining companies may be expected to be as much for 1916 as for 1915 and 1914 combined. During last year the total was \$1,586,829, and for 1911 \$1,689,331, a total of \$3,276,161. By the middle of November, 1916, total disbursements of companies will be in excess of \$2,900,000, and there will be the customary periodical dividends for the remaining weeks of the year to a total of nearly \$100,000, so that it is reasonable to expect this year's dividends to reach a total of \$3,300,000.

Another evidence of progress is found in the larger number of mining properties that have shipped more or less ore this year. For instance, there are a dozen mines on the East Kootenay list of shippers to Trail, compared with four in the corresponding period of 1915 and that of two in 1911. True, most of these have shipped only small quantities of ore, but the fact that they are producing at all after years of inactivity is regarded with some satisfaction. In degree, other older mining districts are also giving evidence of a revival of interest in mining.

The total of ore receipts at the Consolidated Mining & Smelting Co.'s works at Trail for the 10 expired months of 1916 is 416,551 tons, of which quantity 315,722 tons was from mines operated by the company, and 70,829 tons was of custom ores. By far the greater part of the ore mined by the company came from its mines in Rossland district, and in East Kootenay, the proportions of the several large producers, having been, Centre Star group, Rossland, 1,09,335 tons; Le Roi, Rossland, 104,271 tons; Sullivan, Kimberley, East Kootenay, 76,816 tons. When compared with 1915 and 1914, the 1916 total to November 1 shows a marked increase, as the quantity of ore received dur-

ing the corresponding period of 1915 was approximately 372,000 tons, and in 1914 329,000 tons. The chief increase was made by the Sullivan mine, which shipped 40,700 tons more in 1916 than in this period of last year. Other increases included 6500 tons from the Boundary district (from the company's Emma mine), 3700 tons from Ainsworth mining division of West Kootenay, 2800 tons from the Slocan divisions, a similar increase from United States mines, 1600 tons from Kamloops division of the Yale district, and several minor increases. Partly offsetting these gains was a decrease of about 12,000 tons from Rossland mines, resulting from temporary curtailment of smelting gold-copper ore, owing to shortage of coke for the blast-furnaces.

The Ainsworth mining division of West Kootenay maintains

SLOCAN STAR MILL AND DUMP AT No. 10 ADIT, NEAR SANDON.

its number of ore-shippers to Trail, but two-thirds of the number have only sent small quantities. Of the others, the Bluebell is in the lead for 1916 with total to the end of October of 4069 tons, chiefly of lead concentrate; next comes the Highland with 2645 tons of silver-lead ore, and then the No. 1 with 2381 tons. The Utica has shipped 839 tons; tenders are being invited for driving a deep-level adit at this mine, to open the ore-shoots at about 350 ft. greater depth. The Florence company's total is 834 tons; a considerable output from this property is being prepared, the erection and equipment of a concentrating mill being well advanced. The Comfort, which adjoins the Bluebell group, has shipped 435 tons of lead ore and is expected to continue making an output.

In the Slocan and Slocan City divisions many properties are being worked, including a number that had been idle for years; altogether, 26 are on the Trail list, while two or three others ship zinc ore to the United States. The Standard has this year shipped 3682 tons of silver-lead ore and concentrate to Trail, beside a comparatively large quantity of zinc concentrate to the United States. The Rambler-Cariboo's total is 1598 tons of silver-lead concentrate; its zinc concentrate is now being shipped. The Galena Farm has sent 1367 tons of silver-lead product to Trail, and much zinc concentrate to the

United States. The Slocan Star has shipped 924 tons of silver-lead, and considerable zinc concentrate.

To provide for the cost of re-modeling its concentrating mill, increasing its power-supply, and constructing an aerial tram, some 2300 ft. from mill to railway, the Slocan Star Mines last May raised \$70,000 by the sale of bonds, and later obtained \$10,000 more to complete these improvements. The hydro-electric installation included 9320 ft. of wire-woven wood-pipe, to deliver water under an effective head of 480 ft. to a 51-in. Pelton wheel developing 400 h.p., to operate a 15-drill compressor, and electric generators to furnish auxiliary power. Air for mine purposes is conveyed 2700 ft. in a 6-in. steel pipe. The mill building has been enlarged by a 25-ft. extension, and a 40 by 40-ft. new structure erected to house a flotation tank. The new plant includes a Dorr thickener and Portland filter, while to the mill equipment has been added four Frue vanners, five Deister-Overstrom tables, centrifugal pumps, and a Hardinge 6-ft. conical mill. Additions to concentrating plant have increased the daily capacity from 70 to about 170 tons. Ore-shoots are opened on No. 6, 8, 9, and 10 levels; on the last mentioned the shoot averages between 6 and 7 ft. wide, chiefly of milling ore but with clean galena in parts. Prior to 1906 silver-lead ore to a gross value of \$1,291,728, silver-lead concentrate \$1,229,641, and zinc concentrate \$154,061 (total \$2,675,430) were shipped. Then followed years of extra-lateral right litigation until, several years ago, conflicting interests were merged, and now the outlook is favorable for renewed profitable operation.—Other Slocan mines contributing appreciably to the output of the district are the Hewitt, Idaho-Alamo, Lucky Jim, Lucky Thought, Noonday, Ruth, and Wonderful.

In the Nelson division, the Emerald (lead), Molly Gibson (silver-lead), Eureka (copper), Queen, Granite-Poorman, and Relief (all three gold), and Hudson Bay (zinc) are the chief producers. Work is being resumed on the Silver King (silver-copper) after two years of inactivity. Rossland mines have shipped 269,287 tons of ore to Trail in 10 months of 1916. In Boundary district, the Granby and B. C. Copper companies continue to make a large output and in the last three months the Consolidated company has shipped to Trail 6889 tons of copper ore from its Emma mine. In the Similkameen, the Hedley Gold Mining Co. is the only important metalliferous producer; the Princeton Colliery has lately increased its output of coal. There is gradual improvement in Yale district; the Iron Mask, Kamloops, has shipped to Trail this year about 2700 tons of copper-gold ore. Small shipments are being made from Nicola Valley region; the Highland Valley company has commenced operating a concentrating plant in Ashcroft division. In the lower Coast district, the Britannia company is making a considerable output of copper ore. In the upper Coast district, the Tonopah-Belmont company is erecting a gold-milling plant on Princess Royal island; the Granby company is providing additional power supply to overcome present restrictions. In the Skeena country development is being continued. On Vancouver island the coal mines are making a larger output than that of last year.

BUTTE, MONTANA

BUTTE & SUPERIOR EARNINGS.—TUOLUMNE PROGRESS.—EMMA ZINC.—BUTTE-DETROIT MILL.—ANACONDA ZINC-ORE SCHEDULE.—ELM ORE.

The Butte & Superior dividend for the quarter ended September 30 will be considerably less than recent distributions. The net operating profit was \$947,901, equivalent to \$3.27 per share. The profit for the first quarter was \$3,554,940, and for the next period \$2,062,029. The grade of ore was about the same in the three periods, averaging over 15% zinc and 6 oz. of silver per ton. There was a decrease in the tonnage of ore treated during the third quarter, due to an accident in the shaft that caused a suspension of operations for 11 days.

The cost of mining and milling was \$7.10 per ton, compared with \$6.26 for the second quarter. The average price received for spelter was 8.3c. per pound. Earnings for the quarter ending December 31 will show a considerable increase. The output will be greater, and spelter is realizing a much better price. After disbursements for the dividend of the second quarter, amounting to \$6.25 per share, the company had net quick assets of approximately \$2,700,000. The company now has outstanding 290,197 shares, as 17,500 were recently issued to purchase 35,000 shares of American Zinc, Lead & Smelting Co. The consolidation of the two companies has been much discussed, and it would be of great benefit to the Butte & Superior, as it would provide a selling agency and would result in a much more satisfactory settlement for the silver-content of the ore. The concentrate shipped to the zinc smelter averages over 21 oz. of silver per ton. The silver remains in the retort-residue, and its recovery is expensive. If the companies are consolidated a small plant will no doubt be erected to treat this residue. The offer of one share of Butte & Superior for two of American Zinc as a basis for taking over the balance of the stock was turned down. An appraisal of the American Zinc plants was made recently, and it is probable that a new proposal will be made to trade two shares for three. The hoisting equipment for the new shaft is slow in arriving, and it will not be ready to hoist ore before next April. Meanwhile timber and supplies will be hauled through this shaft with a geared electric hoist.

The Tuolumne has re-timbered the shaft on the Sinbad claim, unwatered the mine and cleaned-up the 500, 600, and 700-ft. levels. A cross-cut will be driven on the 700-ft. level to the south side-line of the property, a distance of 1200 ft. The mine is now in a position to make regular shipments from ore developed in the upper levels. A new hoist is being installed at the Colusa-Leonard shaft, and a new head-frame will be erected. About 60 tons of ore per day is being hoisted through the Tuolumne shaft; this will soon be increased to 100 tons per day. A winze has been sunk on the vein from the 2600 to the 3000-ft. level. Exploration will be done at the 2800 and 3000 ft., and if results are encouraging the shaft will be deepened to facilitate ore extraction.

The Emma mine is shipping zinc ore to the Washoe works. The Emma is in the centre of the residence district of Butte, and it is necessary to haul the ore over the city streets. Six horse-teams are used to haul the ore, and it is not likely that they will be replaced by auto-trucks, as these have a hard time getting up the hills when they are covered with ice and snow. The ore is concentrated at Anaconda and then shipped to the electrolytic plant at Great Falls. The Emma is the property of the Butte Copper Zinc Co., and is being operated by Anaconda under an option agreement. Anaconda has taken an option on the Bonanza, Andy Jackson, and Geneva claims in the south-west part of the district. Shaft-sinking has been started on the Bonanza, and a cross-cut will be driven on the 1000-ft. level to explore for zinc and silver. The claim adjoins the Travona and Ancient claims of W. A. Clark, well-known silver producers in the early days.

The Butte-Detroit Co. has ordered flotation equipment for its 150-ton mill. It was expected that this plant would be operated as a custom zinc mill, but negotiations are under way with the Davis-Daly to supply zinc ore until such time as the Butte-Detroit develops enough ore in the Ophir mine to keep the mill at work. Nothing has been done on the Ophir for more than a month, apparently because of lack of funds. The shaft is 1065 ft. deep; but no development has been done below the 500-ft. level. The Ophir is well situated; it made a good showing as a silver mine, and it warrants development at depth. Davis-Daly has several drifts in ore, from 6 to 10 ft. wide, that averages 50% zinc and 12 oz. silver per ton. Flotation tests on the ore indicate that a 53% zinc concentrate can be made with a recovery of 95%. The low iron-content makes the ore desirable for treatment by flotation.

The Anaconda company is now buying zinc ore for the leaching plant at Great Falls. A tentative schedule has been drawn up for ore containing not less than 10% zinc. The company pays for

- 100% of the zinc-content at 1½c. per pound.
- 80% of the silver-content at market price.
- 80% of the gold-content at market price.
- 70% of the copper-content at 6c. less than market price.

The treatment charge is \$1.50 per ton. The schedule is based on a market price for zinc of 9c. per pound. No doubt shippers will be paid more for zinc when the details of the leaching process are worked out. The treatment charge is low, and there is much silver-zinc ore at Butte that can be mined profitably under this schedule. The old silver mines were forced to shut-down when they opened zinc ore because of the penalty imposed by copper and lead smelters. Now the zinc will pay the cost of mining and smelting, and the money derived from the silver-content is all profit.

The Elm Orlu is mining 500 tons of zinc-silver ore per day. A new electric hoist has been installed, and the shaft has been sunk to the 2200-ft. level. Skip-chutes will be cut on several levels, and when alterations to the mill are completed the output will be doubled. The copper-bearing slime from the old Butte Reduction Works is being put through the flotation department, and this brings the mill-feed up to 800 tons daily. The Clark interests are also opening the Evelyn mine in the Walkerville district. On the 300-ft. level a drift is being driven on a narrow vein of high-grade zinc-silver ore.

LEADVILLE, COLORADO

MONTHLY OUTPUT.—LABOR SITUATION.—MIKADO SHAFT.—EMPIRE ZINC CO.'S MINES.—DOWN TOWN MINES.—JULIA MINING CO.—U. S. S. R. & E. CO.—FRYER HILL.—BEEBE HILL.

The monthly output of the district continues to grow. In October, 80,500 tons of ore of various grades and metal-content was sent to the smelters. The entrance of the Penrose, Cloud City, and Tip Top into the list of producing mines has materially added to the tonnage. These properties will increase their output steadily and several others, notably the Greenback, Mikado, McCormick, and Hilschle will be shipping before many weeks have passed.

Although mine-owners feel concerned over the labor situation, it is generally thought that no trouble will be forthcoming from that source for several months at least. The Union authorities have taken a stand against strikes, stating that more can be secured for the betterment of their cause by open and above-board arbitration with the operators, and unless the radical element gains control of the local branch there appears to be little cause for anxiety for the time being. No change in the situation has occurred. The managers continue to stand pat on their refusal to treat with the Western Federation of Miners. The State Industrial Commission has taken no steps in the matter. The Union men are steadily pushing their organizing campaign, and the crisis that was expected immediately following election has not materialized. The strike that was supposedly pending last month has ceased to be the main topic of conversation, and is only occasionally referred to as a possible happening of the future. The probability of a strike being called at some future date, possibly early in the spring, is now holding up several new concerns that were contemplating entering the district. The continued effort put forth by the Unionists to increase their membership is disquieting to the operators who are now actively engaged and who plan future development. For this reason, the labor agitation has been extremely detrimental to the progress of extensive mining here, and unless a definite decision is reached soon its effects will continue to be felt for some time to come.

George O. Arcall, manager of the Iron Silver Mining Co., is completing an exhaustive scheme of preparatory work at

the Mikado shaft on Iron hill, where he contemplates the extensive development of a large area of rich territory. The shaft has been re-timbered to water-level, a depth of 900 ft. New surface buildings have been erected, including an engine-house, machine-shop, blacksmith-shop, and office. The machine and blacksmith-shops have been thoroughly equipped. A 300-hp. Wellman-Seaver-Morgan hoist has been installed in the engine-room. The hoist is the largest in Colorado. Pumping machinery is expected to arrive during the month; unwatering will be started before the beginning of 1917.

The Empire Zinc Co. is carrying on extensive preparations at its newly acquired holdings, the Robert Emmet and McCormick properties on Yankee hill. The Emmet shaft is being repaired throughout its depth of 900 ft. All the important drifts are being enlarged and re-timbered, and all the underground workings are being put in order for a large tonnage from the immense bodies of high-grade lead, zinc, and silver ores that have been uncovered. The main shoot, which is one of the largest here, continues strong in the deepest workings of the Emmet, and it is planned to sink the shaft early in the coming year. The drainage that has been undertaken through the Wolfstone and Greenback shafts at the instigation of the Empire company has completely drained the Emmet, and it will be possible to add several hundred feet of depth without encountering water. Surface preparations are also being made for efficient handling of the output, which will not reach its maximum next year.—Similar work is being undertaken at the McCormick shaft adjoining the Emmet. The old drifts are being put into shape, and new ones are being driven to cut the orebodies. On the surface, a new railroad switch is under construction to the property, and a new trestle from the shaft to the siding is being erected. These two properties are expected to figure greatly in the output of the district during 1917.

Unwatering of the Greenback shaft, which is being done by the Empire Zinc Co., is progressing steadily. New auxiliary pumping machinery has been installed on the 1100-ft. level. The Layne-Bowler sinking-pump has been connected with the station equipment, and is now lowering the water in the shaft, which is 1250 ft. deep.

The Down Town Mines Co., which has just completed unwatering the large Down Town basin, is now extracting ore steadily through the Penrose shaft. One of the largest bodies of iron-manganese uncovered in the district has been discovered in the Penrose, in ground lying between the old Coronado and Midas shafts. The output is 2000 tons per month. Aside from mining ore, extensive exploration is being done in new territory with a view to opening bodies of carbonate of zinc which are believed to exist throughout this section. The pumps continue to raise 2500 gal. per minute. On the surface, the lack of proper dumping room has necessitated the erection of a long trestle over Orange street to the east of the shaft several hundred feet. The new construction will make available a large space of vacant ground.

The manager of the Julia Mining Co., Clarence Jarbeau, has just completed the driving of a connecting drift from the Cloud City to the Home Extension, a work that was undertaken for the purpose of decreasing the cost of transporting ore. For several months, a large quantity of iron-manganese has been extracted from the Home Extension, where an immense body has been developed. The property is so isolated from railroad service that the ore had to be hauled by team to the nearest siding. The Cloud City, on the other hand, is close to the main line of the Colorado Southern, which runs through the city to the outlying mines, and any ore hoisted through the shaft can be loaded into the cars. The two shafts are less than a quarter of a mile apart, and the orebody lies between them, a fact which has made the driving of the connecting drift doubly advantageous. At present 100 tons daily is being extracted through the Cloud City, and a steady output is still being hoisted through the Home Extension.

The Leadville Unit of the U. S. S. R. & E. Co. is now draining the Jamie Lee shaft on Fryer hill. This shaft is to be sunk 300 ft. as soon as unwatering is completed. The manager, Howard S. Lee, has just made known a decision of the company whereby a good deal of the ground on the upper levels of the Tip Top property is to be blocked and leased. Operations at the Leadville Unit are being followed with keen interest by local mining men, as the developments planned will for the first time reach the formations in the second contact.

In charge of Warren F. Page several diamond-drill holes are being put into Fryer hill from the lower levels of the Progressive shaft. This and surrounding properties have been rich in silver-lead ore, which was found in pockets. No strong and continuous ore-shoot has been uncovered, and the drilling is being done in an effort to find the main vein. No work has been done in this area for a number of years, the revival being due to the draining of the entire section by the Leadville Unit.

The Little Jonny and other properties on Breece hill, controlled by the Ibez Mining Co., are rapidly coming to the front as producers of low-grade copper ore. These rich gold mines of the 90's are now yielding several hundred tons of 6 to 8% copper ore to the district's total, and it is stated that the most recent developments in the Ibez properties indicate a large increase in the copper output.

LEWISTON, MONTANA

DEVELOPMENT IN LITTLE BELT MOUNTAINS.—CYANIDING TAILING.

The high price of metals has stimulated prospecting and development in the eastern part of the Little Belt mountains during the past summer, after many years of quiet. The principal work has been done on the Yankee Girl mine on Running Wolf creek, from which several carloads of lead-silver-zinc ore has been shipped to the Anaconda's new electrolytic zinc plant at Great Falls. The mine was located in 1894, and some rich ore was hauled by wagon to Great Falls, but the lower grade could not pay for such a long haul and little was done with the property until recently. At present 12 to 15 men are employed and several teams are engaged in hauling ore to Stanford, the railroad shipping-point. The orebodies on Running Wolf are replacement deposits in limestone near the contact with porphyry; they have proved to be small and pockety in the past, but an extensive orebody is now thought to have been discovered. Work is being done on adjoining claims, and even if the shoots prove small they will pay to mine and ship at present prices. Paris Gibson and associates of Great Falls have applied for patents on 30 claims containing high-grade hematite, assays giving over 50% iron; the claims are also on Running Wolf creek. Several mines near Barker, Monarch, and Neihart are producing lead and zinc ores regularly, carrying silver and gold. The zinc ore is shipped to Great Falls.

One of the first places to use the cyanide process in the United States was at Giltedge, on the south side of the Judith mountains, in the early 'nineties; the process was not well understood at that time, and the extraction varied from 90% down to practically nothing. As a result, part of the large tailing-pile contains nearly as much gold as when first mined. Turnbull, Caldwell, and Allen are re-working part of this material, said to average \$1.50 per ton, in a small cyanide plant. They have no way of heating solutions in vats, however, so during cold weather operations are suspended.

The Spotted Horse, Maginness, and Cumberland mines at Maiden are being regularly operated by lessees. Since the discovery of the orebody in the Cumberland last spring the lessees have produced \$75,000 in gold, largely in ore shipped to Anaconda. A recent clean-up of the cyanide mill gave \$7000.

Kansas people are to drill for oil and gas near Winifred; the area is favorable for their occurrence.

TORONTO, ONTARIO

OIL PRODUCTION.—COPPER AT PORT ARTHUR.—NICKEL PLANTS.

Much attention is being given to the active and successful development of the Thamesville oil-field in south-western Ontario by the Vacuum Gas & Oil Co., which controls a large acreage and has undertaken operations on an extensive scale. The Thamesville field, which is 50 miles west of London, is not a new oil area, having been about 10 years ago the scene of operations that were considerably more successful in extracting money from the pockets of over-credulous investors than oil from underground. Such actual development as was then undertaken was badly mismanaged, and the field was soon abandoned. It is in the same belt as Petrolia where producing oil-wells have been in operation for 50 years, and the Bothwell pool, which has also a long record as an oil producer, is only $4\frac{1}{2}$ miles distant. The Vacuum Gas & Oil Co., which only commenced active field work five months ago, has already seven producing wells, the most important of which, the No. 1 Featherstone, produces 150 bbl. each 24 hours, with a number of others in various stages of development. Power for pumping is supplied by a gas engine and plant capable of operating 25 wells, which will constitute the first unit. The company having secured control of 800 acres, is planning to add two other units, making a total of 100 operating wells. In addition to its Thamesville holdings the company has 2500 acres in the Brooke oil-pool, and the Kent and Essex County oil-fields, and extensive gas interests. One large gas flow has been secured in the Tillsonburg area, and other gas-wells are being put down. The oil from the Thamesville well is shipped to the Imperial Oil Co.'s refinery at Sarnia. It is high grade, containing 24% benzene and 16% gasoline.

Lately there has been a noteworthy revival of activity in copper mining in the Port Arthur district. The Tip Top mine, 82 miles west of Port Arthur on the Canadian Northern Railway, shipped 340 tons to the smelters last winter. Returns encouraged more energetic development. An extension of the vein was discovered 1000 ft. from the shaft, and another vein was found 26 ft. wide, of which 15 ft. was high-grade ore. This mine has now 20,000 tons on the dump and in the stopes, carrying about 6% copper with small gold and silver-content. A spur-line is being constructed from the mine to connect it with the Canadian Northern, and when this is completed ore will be shipped to the smelters at the rate of 100 tons per day.—The Mine Centre Copper Co. holds under option a claim 3 miles west of Mine Centre on which a discovery was made by Arthur E. Stone last May, comprising a vein 80 ft. in width which has been exposed for 350 ft. The ore has been found to improve in value with depth. Returns from two carloads shipped to the Trail smelter yielded \$1875 gross. Sixty tons per day is being taken out.

The plant of the International Nickel Co., now under construction at Port Colborne, Ontario, will be on a somewhat more extensive scale than originally contemplated, the company having set aside \$5,000,000 for increasing its Canadian equipment. This, however, includes the enlargement of its smelter capacity and an increase in its power. The company is anxious to get the foundations of its Port Colborne refinery completed before the frost sets in, and if this is accomplished expects to be refining nickel within 12 months. The plant will be built in units, so that it can be quadrupled if necessary.—The British-America Nickel Corporation, originally incorporated as the Canadian Nickel Corporation, the refinery of which will probably be in the neighborhood of Welland, will have its smelter near the Murray mine in the Sudbury district, and has already men at work on a power-plant. It now controls 17,000 acres of Sudbury nickel lands, and has obtained the Canadian right to a Norwegian process known as the Hybinette, by which it is claimed that nickel 99% pure can be produced.

ALLEGHANY. A 10-stamp mill is to replace the roller mill at the Twenty-one mine.

AMADOR CITY. Results at a depth of 850 ft. in the Original Amador are officially reported as most satisfactory, the ore being of better grade than on upper levels. Sinking to 1500 ft. is to be started early in December. The mill has been remodeled. By adding an 8 ft. by 22-in. Hardinge ball-mill, and an 8 ft. by 36-in. pebble-mill, these and 20 stamps are crushing 250 tons daily, a gain of 150 tons. The recovery is 90%. The tailing dam has been made 6 ft. higher. A. A. Busey is superintendent.

COLFAX. Reports from the Iowa Hill district state that a large deposit of chrome has been discovered.

HAPPY CAMP. A mill and cyanide-plant are to be erected at the Bradley mine on Independence creek in Siskiyou county. A 12-mile road is being constructed.

JAMESTOWN. The Sierra Nevada Exploration Co., which is operating on Turner's flat, three miles south-west from this place, sinking shafts to open the ancient gravel-channel running along and under Table mountain, is building an electric power-line to connect with the line of the Sierra & San Francisco Power Co. near Montezuma. This is for current to operate the large Neilson pump and electric hoist now being installed. The depth to bedrock where the shaft is being sunk is about 90 feet.

NEVADA CITY. The new 10-stamp mill at the Ocean Star mine, near Washington, was destroyed by fire last week. The property is operated by the Columbia Mines company. The plant is to be re-built. E. C. Klinker is manager.

SMARTSVILLE. The old Blue Point hydraulic mine is to be re-opened by Sidney Wood and others. A water supply has been secured, and gravel can be prevented from going into the river.

COLORADO

DENVER. The entire assets of the United States Reduction & Refining Co., recently sold by the U. S. Court to The Golden Cycle Mining Co., have been purchased from them by the Morse Bros. Machinery & Supply Co. of Denver, who will dismantle the mills. The Standard plant at Colorado City had a daily capacity of 1000 tons embodying chlorination, concentration, and cyanide-plant; crushing was done by rolls and tube-mills. Fifteen hundred horse-power in individual induction-motors drove the machinery. The chlorine gas used in the process was made at the plant. The Union mill at Florence was a 700-ton concentration and chlorination plant, crushing being done by rolls. Electricity generated at the plant with steam supplied current for the motors used there. The U. S. Smelting Co. at Canon City had a smelter making zinc-lead white from zinc-sulphide ores. The plant had a daily capacity of 700 tons. The Bimetallic plant is a modern cyanide-plant of 500-ton capacity for treating tailing from the old Bimetallic mill destroyed by fire several years ago. The dismantling of these plants marks the passing of chlorination treatment of Cripple Creek ores, and is the answer to the controversy waged 10 years ago as to the relative merits of the two processes. The U. S. Reduction & Refining Co. had a capital of \$6,000,000 common, \$4,000,000 preferred, and a bond issue of \$2,650,000. This is the largest purchase of milling plants ever made in the West, and adds quantities of nearly every kind of machinery to the firm's stock. In these plants there is 15,000 tons of machinery, 5000 tons of structural steel and buildings, 2000 tons of pipe, 300 tons of lead, 45 tons of copper wire, 12,000,000 ft. of lumber and 10,000 squares of corrugated iron. Over 1500 acres of land with water-rights was also included.

SILVERTON. Ore shipments during the past week totaled 34 carloads, also 13 to the Silver Lake mill for treatment.

The Pride of the West and Green Mountain mines' mill has been overhauled and is now treating 100 tons daily. Motors and flotation apparatus were installed.

Work is to be continued through the winter at the Champion mine on Sultan mountain, a mile from Silverton.

IDAHO

NINE-MILE. The Alameda Mining Co., which owns and is developing the Alameda mine, control of which recently was acquired by Spokane men, has been awarded \$56,070 by the referee, Lawrence E. Worstell—as the value of the ore alleged to have been extracted from its ground by the Success Mining Co.—who heard the testimony in the case under appointment by Judge Woods of the district court. This award bears interest at the rate of 7% per annum from June 1, 1913, which November 1, 1916, amounted to approximately \$13,410, making the total award with interest, \$69,450. The referee found that on or about April 1, 1912, the Success company commenced to extract ore from Alameda ground, and continued to do so up to August 1, 1914. The trespass, however, according to the report and findings, was committed under an excusable mistake, and the removal of such ore was through inadvertence in the honest belief that it was the property of the Success company. The total amount of the trespass committed on the 400-ft. stope, according to the findings, equals 25,695 cu. ft., and on the 450-ft. level 13,442 cu. ft., while the foot-wall area on the 700-ft. level amounted to 10,323 cu. ft. A ton of ore on the 400 and 450-ft. stopes was found to be equal to 7.49 cu. ft., which assayed 20.45 oz. silver, 20% lead, and 23.95% zinc. On the 700-ft. level it took 8.86 cu. ft. of ore for a ton, and its assay value was 7 oz. silver, 7.5% lead, and 25.7% zinc. The referee adopted the average prices of metals as testified to by Rush J. White as a basis for the value of the ore extracted, which were: 58.78¢. per ounce for silver; 4.236¢. per pound for lead; and 5.188¢. per pound for zinc. It was stipulated during the trial that the mill saving was 56% silver, 72.5% lead, and 65% zinc. The Success contract in force between April 1, 1912, and August 1, 1914, was used by the referee as a basis for computing the freight and treatment charges, and that the reasonable cost of mining and milling the ore was \$2.21 per ton, and that the Success company was entitled to those costs.

The Idaho Supreme Court has reversed the decision of Judge W. W. Woods of the District Court of Shoshone county in the Alameda-Success ore-trespass case, in which it was alleged that the Success company had entered Alameda ground and extracted ore valued at more than \$56,000, according to the findings of the referee, Lawrence E. Worstell. The District Court erred in not making a direct and positive finding as to whether the apex of the Granite vein of the Success company is within exterior boundaries of the claim. The Superior Court concluded that under the evidence the said Granite vein has its apex within the boundaries of the Granite claim. The case will now go to the U. S. Supreme Court.

MICHIGAN

HOUGHTON. Calumet & Hecla reports the following yield for October, in pounds:

Mine	October	10 months
Ahmeek	1,976,977	19,662,663
Allouez	984,126	8,633,609
Calumet & Hecla	6,623,499	63,824,854
Centennial	190,600	2,018,845
Isle Royale	1,035,580	10,261,805
La Salle	121,432	1,075,921
Osceola	1,555,921	16,490,721
Superior	221,162	2,575,692
Tamarack	582,225	5,531,409
White Pine	374,466	3,654,608

The Baltic, Champion, and Trimountain mines of the Copper Range company are maintaining a large output of good ore.

The C. & H. has 21 furnaces in blast at Hubbell. Another furnace is ready to go into commission at Dollar Bay, making

seven at this plant. Good progress is being made at the new foundry.

To increase its output the Osceola company wants more men.

Daily output of the Ahmeek is over 3500 tons of ore, also large quantities of mass copper.

A turbo-generator is to be installed at the Mohawk, to be driven by exhaust steam from the stamps.

MISSOURI

JOPLIN. Cold weather is already curtailing mining and milling operations. Pressure of natural gas is low, and coal may have to be used for a while.

The range for zinc ore last week was between \$85 and \$95 per ton for 60% product, a gain of \$5. The output of the region was 5819 tons of blende, 676 tons of calamine, and 1901 tons of lead, averaging \$86, \$48, and \$85 per ton, respectively. The total value was \$601,952. Miami, Oklahoma, led in production, followed by Webb City-Carterville. The A. W. C. Mining Co. of West Joplin sold 1500 tons of blende on a base price of \$95 per ton.

MONTANA

BUTTE. Cold weather has been interfering with mining operations, ore freezing in bins and cars.

A shaft-house, 70-ft. head-frame, two 125-hp. boilers, hoist, air-compressor, and other equipment are complete at the Great Butte Copper Co.'s mine, two miles north of Meaderville. The shaft has been unwatered and repaired to a depth of 420 ft.; it is 1025 ft. deep.

The new Nordberg hoist for the Davis-Daly has reached the mine. Two cables have also arrived.

From its 2000 and 2200-ft. levels the North Butte is extracting 17% zinc ore. Shipments are to be increased to 300 tons daily. The Anaconda company buys this ore.

To pay for a pump, etc., the Butte-Great Falls company has made an assessment of 5c. a share. A heavy flow of water has been encountered.

One hundred pounds of powder set off at the Bullwhacker mine last week broke over 4000 tons of 5½% copper ore.

The semi-annual meeting of the Montana Section of the A. I. M. E. was held at the Silver Bow Club, Butte, on November 10. This was a postponement of the regular October meeting in order that the members might enjoy the presence of L. D. Ricketts, president of the Institute. Mr. Ricketts spoke for some time on the subject of committee work as applied to technical research. He covered the progress of mining and metallurgy, including possibilities in flotation. B. B. Thayer gave a talk on his recent trip to South America with Mr. Ricketts, Reno Sales, and others. F. G. Cottrell discussed the work of the U. S. Bureau of Mines. He stated it to be the fact that at Anaconda the weight of gaseous products going to waste through the stack was 20 times that of the slag. H. S. Ware, assistant superintendent of the Anaconda smelter, followed with an interesting account of some of the points in connection with the Institute meeting in Arizona. C. W. Goodale and C. R. Kuzell spoke on their recent trip through Arizona. F. E. Marey discussed separation of tailing at small mines. Reno Sales described some conditions in South Africa. C. L. Berrien of the Anaconda compared mining systems, while Frederick Laist mentioned dust losses.

NEVADA

BATTLE MOUNTAIN. The old Dean gold mine has been reopened with J. R. Farrell in charge. A mill is to be built.

EURKA. The Eureka Mining Bureau, composed of local mining and businessmen, are interested in securing syndicates that may be in position to operate meritorious properties requiring some development. The Bureau calls attention to the following groups of claims, which are strongly recommended by local operators having direct knowledge of the conditions: (1) Five claims developed to 350 ft. depth. A 2300 ft.

adit has explored to a depth of 1000 ft. Reserves blocked out are estimated as 75,000 tons of gold-silver-copper ore. Some method of local treatment is necessary. This property can be bonded on reasonable terms for \$75,000, with royalty on shipments of 15%, first payment six months after examination. (2) Thirteen claims on opposite side of mountain to No. 1 group. Two adits driven, one in 2300 ft., the other 800 ft., and one shaft down 400 ft. Thirty shoots are exposed. Shipments aggregate \$600,000. The price is the same as for No. 1 group. (3) The erection of a custom plant is urged as a profitable undertaking to treat the gold-silver ore. At least 50 tons daily could be expected at first, with an increase when the plant started. (4) Electric power is assured if present plans mature. A. G. Hillen is secretary.

GOLDFIELD. A large station has been cut at 100 ft. in the Silver Pick Con. The shaft is in quartz of good quality, in which are seams and masses of gold-copper ore. G. F. Dyer is in charge.

The Hornsilver Milling, Mining & Water Co. has been organized to treat ore at Hornsilver.

RAWHIDE. Reports indicate that in a small though steady way this old place is being actively worked.

ROCHESTER. At a depth of 800 ft., from winze 301, the Rochester Mines Co. is driving in good ore. The October output was about \$55,000. Good progress is being made in enlarging the mill.

White quartz containing ruby silver has been opened in the Nevada Packard mine. The daily output is about \$1200 of silver.

NEW MEXICO

The aerial tram from the Pacific mine to the Socorro M. & M. Co.'s plant, one mile distant, has been completed, tested, and found to operate perfectly. The adoption and placing in commission of this system of transporting the Pacific ore marks the end of an era of operation during which 11,162 tons of ore worth \$171,585 was mined in a crude way, and shipped to local custom mills by burro-train. While the general average of ore mined in the Mogollon district for the same period has been around \$12 per ton, that from the Pacific had an average of \$15.37. With the more adequate mining facilities now employed, in connection with modern tramway delivery to mill, the property may be expected soon to eclipse its past record and take rank with the best producers here. Operations are being conducted by Socorro M. & M. Co. under agreement with the Oaks company.

Mogollon, November 14.

OREGON

SUMPTER. It is said that the old smelter here may be again blown-in by the new owner, J. A. Gyllenberg, to treat ore from eastern Oregon.

TEXAS

(Special Correspondence).—Development of several new cinnabar claims in the Terlingua quicksilver district will be started soon, according to advices received here. It is stated that a syndicate of Houston men, headed by Morris Wexler, has acquired several sections of land in that part of the Big Bend country on which there are outcroppings of cinnabar. It is expected that within a short time all of the mines at and near Terlingua that had lain dormant for the last few years will again be actively worked. While the principal output of quicksilver now comes from the furnaces of the Chisos Mining Co., of which Howard E. Perry, of Chicago, is president, several other companies have resumed development and are extracting considerable quantities of rich ore. The principal mines are those of the Chisos company; the Mariposa Mining Co., of which James Normand of Marfa, Texas, is president; the Texas Abandon Mining Co., of which Henry Hill of Clifton, Arizona, is president; the Study-Butte Mining Co., of which

W. B. Burham is manager; and the Big Bend Mining Company.

Outcrops of cinnabar ore have been discovered east of Terlingua about 60 miles, but so far no steps have been taken toward their exploration. The quicksilver belt also extends across the river into Mexico from Terlingua, and at the time the revolutionary period in that country commenced, several promising claims of cinnabar ore had been filed and were about to be developed.

Terlingua, November 11.

UTAH

ALTA. In the Alta Gladstone mine some of the ore contains from 1 to 8% molybdenite. Development is to be continued through winter, and a mill may be erected in the spring.

The Cardiff Mining Co. paid 25c. per share on December 1, a total of \$125,000. The daily ore output is over 100 tons averaging \$35 per ton.

GOLD HILL. Interest in the Deep Creek district is rapidly increasing, more so as the Western Pacific is constructing a railway into the region. Last week 45 claims in the Clifton section were sold to C. L. Glass of Pittsburg for \$100,000. The four groups contain gold, silver, copper, tungsten, and lead ores.

WASHINGTON

DAISY. The Silver Mountain Mining Co., with a capital of 1,500,000 shares at \$1 each, has been organized by Spokane men to take over and operate the holdings of the Daisy Mining & Milling Co. and the Wakkiagin Mining Co. W. E. Seelye of Spokane, is president and general manager, and Charles H. Goodsell of Spokane, deputy United States mineral surveyor, is consulting engineer. The ore contains silver in small quantities. A mill is proposed. A good deal of development has been done.

CANADA

BRITISH COLUMBIA

GOWGANDA. Good progress is reported in development of this district. Lack of transportation hinders shipments of ore, which is silver-bearing.

NELSON. The Norman Mines Co. of Spokane, has taken a lease and bond on the Madison property, on Reco mountain. The bond is for three years at \$25,000, in installments. Andrew G. Larsen of Spokane is consulting engineer for the company, and he already has a small force at work cleaning out the workings preparatory to an extensive examination. The ore is silver-bearing.

PORCUPINE. During October the Dome mine yielded \$185,000 from 40,200 tons of ore, equal to \$4.60 per ton. The total in nearly three years is \$4,369,371 from 905,482 tons, or \$4.76 per ton.

SILVERTON. A large oil-engine is being installed by the Standard Silver-Lead Company to prevent shut-downs caused by ice in the winter.

MEXICO

A Consular Report states that declared exports of crude oil and petroleum products from the Tampico district to the United States in September, reached a total of 1,900,689 bbl., or some 214,000 bbl. less than in August. Of the total, 1,329,337 bbl. was shipped from Tampico and 571,352 bbl. from Tuxpan. Shipments to points other than the United States are reported as 126,435 bbl. from Tampico and 420,497 bbl. from Tuxpan. Therefore the total oil movement from the Tampico fields during September reached 2,447,621 bbl., compared with the August total of 2,872,939 bbl. As usual, only crude oil was shipped from Tuxpan, and nearly one-third of the total went to Coatzacoalcas, Mexico, for refining purposes. The Tampico movement included \$1,572 bbl. of reduced crude, 83,897 bbl. of fuel oil, 78,500 bbl. of distillate, 19,618 bbl. of gas oil, and 1705 bbl. of kerosene.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

H. W. HARDINGE is at Denver.

E. GYBSON SPILSBURY has been in Cuba.

C. S. HALEY has gone to Volcano, in Amador county.

HOWARD D. SMITH has returned here from New York.

R. GILMAN BROWN has returned to London from Siberia.

A. P. ROGERS has returned to New York from Dutch Guiana.

W. F. FERRIER has returned to Toronto from British Columbia.

C. R. CORNING is expected at New York on his return from South America.

CHARLES W. STIMPSON and E. SHORES, of Salt Lake City, were in San Francisco last week.

F. E. GRAHAM BERRY, of Seattle, passed through San Francisco on his way to Sinaloa, Mexico.

RICHARD A. PARKER spent a few hours in San Francisco on his return to Denver, from Oregon.

W. A. CARLYLE is resident director in Ontario for the British-America Nickel Corporation.

GEO. H. GARREY, who recently returned from Alaska and British Columbia, was in San Francisco this week.

BEN. B. LAWRENCE, who was here early in the week, has been appointed a life trustee of Columbia University.

GEORGE M. COLVOCORESSES, manager for the Consolidated Arizona Smelting Co., was in San Francisco for a few days.

J. H. COLLIER has returned to San Francisco from Cook's Inlet, Alaska, where he is manager of the Gold Bullion mine.

FRED. J. BRULE, formerly with the Anaconda company, has been appointed chief engineer for the British-America Nickel Corporation.

CHARLES T. HUTCHINSON, business manager for the MINING & SCIENTIFIC PRESS, has returned from New York and Chicago, after a highly successful trip.

FOREST B. CALDWELL, formerly at the Candelaria mines, has recovered from a nervous break-down, due to Mexican troubles, and is now residing at Woodland, California.

JAMES F. KEMP has improved in health, but the trustees of Columbia University have granted him a further leave of absence for one year so that his recovery may be completed.

H. H. NICHOLSON has returned to San Francisco from Miami, Arizona, and is now on his way to the Plinco mine, Plumas county, California, after which he will return to Salt Lake City.

JAMES DOUGLAS has presented \$100,000 to the United Engineering Society, the income to be used for the benefit of the library. The Trustees of the Society have perfected plans for the development and the extension of the usefulness of this great engineering library, and are endeavoring to secure endowments aggregating \$1,000,000, the income to be used for the library. The plans of the Trustees had previously been approved by Dr. Douglas. Now that the library of the American Society of Civil Engineers has been added to that of the libraries of the Institutes of mining, mechanical, and electrical engineers in the building of the United Engineering Society at 29 West 39th street, New York, the combined library forms the greatest engineering collection in the world. It is the purpose of the Trustees to extend its usefulness, and it is hoped that the splendid endorsement that Dr. Douglas has given will stimulate other similar endowments until the necessary million dollars has been obtained.

THE METAL MARKET

METAL PRICES

San Francisco, November 28.

Antimony, cents per pound	41
Electrolytic copper, cents per pound	25
Pig lead, cents per pound	7.25-8.50
Platinum: soft and hard metal, per ounce	105-111
Quicksilver, per flask of 75 lb.	\$78
Spelter, cents per pound	13
Tin, cents per pound	45
Zinc-dust, cents per pound	20

ORE PRICES

San Francisco, November 28.

Antimony: 50% metal, per unit	\$1.00
Chromite: 40% and over, f.o.b. cars California, per ton	15.00
Magnetite, crude, per ton	8.00
Manganese, 50% (under 35% metal not desired)	16.00
Tungsten, 60% WO ₃ per unit	15.00

New York, November 22.

Antimony. No business is reported. The last quotation was \$1.50 per unit.

Molybdenite: Supplies are small and the demand is fair, holders asking \$1.85 per pound.

Tungsten. Activity has continued, and since the last report several hundred tons has changed hand at \$17 to \$17.50 per unit. The market is firm at the latter figure, with limited offerings.

EASTERN METAL MARKET

(By wire from New York.)

November 28. First-quarter copper is 35.50c, near-by is quiet, lead is active and independents are advancing; spelter is fairly active.

COPPER

Prices of electrolytic in New York, in cents per pound.

Bradley produced 1,918,000 lb. in October. Officials of the company are at Miami, Arizona, studying one treatment, as the plant in Chile is to be greatly enlarged.

Columet & Hecla pays \$25 per share on December \$20, this makes \$75 for the current year. Alouette paying \$3 on January 3, and Columet & Arizona \$1 on December 29.

Magma Copper Co.'s profit in the third quarter was \$311,125, from 2,153,264 lb. of metal, nearly the same as in the June period.

SILVER

The silver market is quiet, with prices steady, the result of steady buying.

Topopah companies have raised wages 50c. per shift from December 1, to remain so as long as silver is above 70c. per ounce.

During the week silver worth \$852,000 was shipped from San Francisco to the Orient. Another lot was valued at over \$500,000.

LEAD

Lead is quoted in cents per pound, New York delivery.

Tin is steady at 45 cents.

ANTIMONY

The market for antimony has been quiet in New York, although a little activity is noted and quotations to advance about 1c.

Asiatic antimony is quoted at 11 to 14.50c, duty paid.

ALUMINUM

The quotation for No. 1 aluminum, 91 to 99% pure, is 30c. The market is quiet.

Eastern Metal Market

New York, November 22.

Copper prices have touched the highest point in many years, in fact, probably never before have future deliveries been quoted at levels equal to those now prevailing. Last week the market was excited, following a rush to cover requirements over the remainder of the year. Great quantities have been taken for the first and second quarters of 1917.

Zinc is active, largely because of buying by the brass mills. This metal also is selling farther than usual into the future, sales having been made to October. Quotations are higher. Sheet zinc is higher.

The leading lead interest is practically out of the market so far as quotations go. The independents are asking up to 7.25c., New York, for prompt. Prior to the advance from 7c., and thereafter, a good business was done.

The tin market has been unusually active, many hundred tons having changed hands. Quotations are higher, but the advance has been moderate.

Antimony is stronger following a short flurry of buying.

Aluminum is unchanged.

Definite information is at hand regarding iron ore prices in 1917. Sales have been made at Pittsburg at an advance of \$1.30 per ton over this year's price, putting old-range Bessemer at \$5.75 per ton, lower Lake port, and Mesabi Bessemer at \$5.50. The non-Bessemer prices are \$5 for old-range and \$4.85 for Mesabi. Bessemer ores have been in unusually heavy demand. Various increased costs make it clear to pig-iron producers that it will cost them at least \$5 more per ton to make pig iron next year. Pig iron has continued active, with buyers especially desirous of covering for next year. Eastern Pennsylvania No. 2 X foundry is quoted at \$26 to \$27, furnace.

COPPER

The market is quiet, but strong. November and December, both Lake and electrolytic, are quoted at 34c., but these positions are scarce, and none too much is available for first-quarter delivery. As matters stand, fractions of a cent seem to count for little in the copper market, and the situation is one which is causing some uneasiness in the trade. No development would be surprising. Prices may go higher, or the market may break sharply without creating wonderment. Last week the market was a runaway, and in the excitement that accompanied the upward movement of prices a large quantity of November and December metal was sought, although sales were restricted by the limited supply. Toward the end of the week 33.50c. was paid for 1916 delivery. First quarter brought 32.50c., and second quarter 31.50c. These prices apply to both Lake and electrolytic, the unusual differentials having been wiped out. Sales for delivery in the first and second quarters of 1917 in the week ended November 18 are estimated at close to 100,000,000 lb. There is still unsatisfied demand. On the 15th, second-quarter electrolytic was sold at prices ranging from 31 to 32c. On the 20th, December alone, also first quarter, was offered at 34c., and sales of second quarter were made at 32.50c., but the latter is now easier around 31.50c. It is reported, but unconfirmed, that prompt Lake has sold at 35c. The suggestion has been made, and a good portion of the trade is considering it seriously, that copper bought for export at comparatively low prices may be thrown on the market if present market levels hold. The great British purchase was made at 25.50c., according to recent information; and the possibility is pointed out of some of this, or similar metal, being sold at a handsome profit, the sellers then replacing what they had sold. The suggestion may be an outcrop of the nervous strain under which the sellers of

copper are laboring. They do not regard present levels as healthy, and ever recurrent in their minds is the thought of what will happen when support is taken away from the market. The base price of sheet copper has been advanced to 41c., mill. The mid-monthly European statistics give the total supply in Great Britain and France, November 15, at 4792 tons, against 5620 tons, October 15. Including that afloat from Chile and Australia, the available supply for those countries, November 15, was 9617 tons against 10,670 tons, October 15. The London market is gaining strength, the quotation for spot electrolytic yesterday being £163, against £152 a week previous. Exports this month are not heavy, amounting to only 13,210 tons from November 1 to 22; but this does not take into account the enormous quantity going abroad in manufactured form. Reverting again to the domestic market, indications point to quieter conditions in the next few weeks.

ZINC

The brass mills have been generous buyers in the past few days, and business has not been checked by steadily advancing prices. Prime Western for prompt delivery was quoted yesterday around 12.50c., New York, and 12.25c., St. Louis, with December delivery at about the same level, first quarter at 12c., St. Louis, and second quarter at 11.50, St. Louis. Consumers are buying farther ahead than has been their habit, and some good-sized orders are booked for the second quarter, with some business to run as far ahead as October. The premium for brass-mill special, over the price of prime Western is near 1½c., this including delivery. Buying of spelter has admittedly not been in proportion to that for copper, assuming that most of the copper is going into brass, a fact which has not yet been explained. Exports continue heavy, those of the month, up to the 22nd totaling 10,587 tons. The spot quotation at London yesterday was £56 10s., or 10s. higher than a week previous. Sheet zinc has been advanced 1c., to 19c., f.o.b., mill, carload lots, 8½ off for cash.

LEAD

A good demand for lead developed this week, following a prolonged period of quiet, during all of which, however, prices held firm. The independents began to stiffen their quotations late last week, and sales of prompt metal were made at 7.05 to 7.10c., New York. Last Monday (the 20th) independents were asking 7.10c., New York, and yesterday, 7.15c., New York. Up to that time the A. S. & R. Co. was quoting 7c., New York, and 6.92½c., St. Louis, but it is generally understood that the company was not selling at those figures. Yesterday it quoted 7.15c., New York, but today no quotations were obtainable. The outside market today is 7.25c., New York, but business is not so active at this level. The spot quotation at London yesterday was £30 10s.,—unchanged when compared with a week previous.

TIN

In the past 10 days a heavy business has been done in tin, in fact, the activity was exceptional. On various days sales aggregated from 200 to 500 tons. Prices advanced under the demand, but only to a moderate extent, the spot quotation for Straits yesterday being 45.12½c. A peculiarity of the market has been that it appeared quiet at most times, even when negotiations for large quantities were under way. The tin-plate mills have bought heavily for their 1917 requirements. The British continue reluctant to issue licenses to ship, and the resultant uncertainty has undoubtedly made consumers see the wisdom of covering their future needs. Up to yesterday only 1275 tons had arrived, and there was afloat 3852. Most of the recent activity has been in future deliveries.

Industrial Notes

Information supplied by the manufacturers.

The Motor-Truck for Mines

The A. A. Haskins Dolomite Company of San Francisco, which owns a large mine of dolomite, containing at least 3,000,000 tons, is using a motor-truck and a 5-ton trailer to haul 40 tons of dolomite every 24 hours from the mine to the nearest railroad siding, a distance of 10½ miles. Exhaustive experiments made by this company prove that the truck and trailer affords a practical outfit enabling the mine-owner to transport this quantity of mineral at a low cost.

Mills making steel by the open-hearth process use dolomite as a flux. It is also calcined to make lime and plaster. The gas, a by-product, is used for charging soda water and other carbonated drinks. The residue after being hydrated makes a durable lime for making plaster ornaments and stucco work; it is used also as a bleach in the manufacture of paper.

and trailer is \$28.71, while with horses and wagons the same tonnage incurred an expense of \$58.21, resulting in a net daily saving to the owners of \$29.50. The truck paid for itself in the first seven months in service.

There are two shifts of drivers and the truck uses 44 gallons of gasoline and 4 gallons of oil to haul 40 tons, registering a total mileage of 84 miles. In the day time 12 gallons of gasoline is consumed and at night 10 gallons for the round trip. The summer days are extremely hot and the nights cool.

The items of cost are as follows:

44 gallons gasoline at 19c.....	\$ 8.36
4 gallons lubricating oil at 40c.....	1.60
2 drivers, 12 hours each, at \$5.....	10.00
Investment interest	} 8.75
Depreciation	
Repairs	
Employers' liability premium	

\$28.71

The mine is in San Benito county and the truck and trailer are loaded direct from a chute into which the dolomite is

MOTOR-TRUCK AND 5-TON TRAILER HAULING DOLomite.

The road from the mine to the railroad is one of the worst for hauling to be found in any part of the country. It is full of chuck-holes and includes 8 miles of crooked mountain road covered with a fine dust 6 to 8 inches deep. There are steep sharp turns with grades from 8 to 10% and 1½ miles long.

Before purchasing the truck and trailer the company experimented with mules and horses. One animal could deliver to the railroad one ton of dolomite every 24 hours. In order to deliver a minimum amount of 40 tons to fill a freight-car, it was necessary to use five teams of 8 horses each, necessitating five drivers and the regular stable help. The cost of this method was prohibitive and was soon abandoned. A rubber-tired truck was then purchased, but the roads were so rough that the trucks could not operate efficiently.

The company was at a loss to solve the problem of getting the mineral to the railroad until they purchased a White 'Goods Roads' truck and trailer. Now they can satisfactorily meet the market demands, the new equipment being able to make 4 trips in 24 hours from the mine to the railroad and deliver 40 tons of material. The drivers are not permitted to drive the truck over 5 miles an hour, tonnage and dependability being more essential than speed.

The cost of delivering 40 tons of dolomite with the truck

dropped. Three minutes is required for this operation. To reach the chute there is a grade of 10% with 12 inches of dust covering the road. The truck pulls the trailer up this grade and a sharp turn with a 40% curve is negotiated in order to get under the chute. A steep drop from the chute necessitates low gear-work to get onto the road. There are no brakes on the trailer and thus the responsibility of holding the 10-ton load on any part of the grades between the mine and the railroad falls on the truck. A short distance from the railroad the road leads for a quarter of a mile across the deep sand and gravel bed of a river, which is always dry in the summer. The road bed was packed with straw to give better traction.

'Pine Flotation Oils' is the title of a pamphlet issued by the PENNSACOA TAR & TURPENTINE Co. of Florida. A flow-sheet is given of the destructive distillation plant, including a concrete retort, used by this firm. This shows the different points at which the various grades come off. The dead wood of the resinous pine is used. This yields 1000 lb. of oil per cord, or say two tons of wood. The retort holds 11 steel cars of one-cord capacity each. These are left in the retort during the process, and afterward are withdrawn containing the resulting charcoal. A list of oils and prices is also given.

EDITORIAL

T. A. RICKARD, Editor

DELIVERY, not sale, of metal is what counts in the present abnormal condition of the market. Our New York correspondent discusses the point in this issue.

FROM the report of the Consolidated Gold Fields of South Africa, which holds a large interest in the Yuba Consolidated Goldfields, we note that the latter company extracted \$2,133,528 in the year ending February 29, 1916. This yield was at the rate of 12.02 cents per cubic yard. The cost was 4.27 cents, so that the profit was 7.75c. per cubic yard. For the five months ended on July 31, the yield was 12.87, the cost 3.7, and the profit 9.17 cents per cubic yard. This is handsome dredging.

AN employer, a senior engineer, or the chief in a department ought to be willing to aid a younger and less-known man without exacting the honor of joint authorship. We see articles published occasionally by two authors, of whom we suspect that the younger has done all the work, while the senior has dotted the i's and crossed the t's, given a little advice, and then arrogated the privilege of halving the credit for the investigation and its presentment. Older and better-known men should be more generous in giving the younger fellows a chance to distinguish themselves without any discount.

HOW the export trade in spelter has grown is indicated by official figures. During the nine months ended on September 30 the total value of shipments was \$42,000,000, as compared with \$21,000,000 in the equivalent period of 1915, and \$3,000,000 two years ago. Of the 275,000,000 pounds included in the shipments this year, 194 million pounds came from domestic ores and 61 millions from foreign ores smelted in this country. The imports of zinc in ore and concentrate amounted to 245 million pounds, as against 73 and 11 millions respectively in the first nine months of the two preceding years.

STEALING a red-hot stove has been considered the last word of larcenous audacity; the theft of gold from a hot retort is not unknown; but these performances are eclipsed by the story told of the removal of half a mile of copper wire from a high-power transmission line through which an electric current of high voltage was passing while the wire was being cut. This can be done, and is often done, by the use of the 'hot-wire' cutter, a shears fixed to the end of an 8-ft. wooden pole and operated by a wire attached to a wooden lever. If copper continues to rise, we may expect to hear of

many thefts like those that used to worry the power companies in Mexico.

COST of producing copper is rising, of course. The management of mines, like domestic economy, suffers in days of excessive prosperity. Wages, supplies, and machinery have risen from 30 to 200%. Of the total cost of mining, 60% is on the pay-roll, and that has risen fully one-third. It is acknowledged that the cost of producing the metal has increased 25 to 30% at the disseminated-copper mines. Similarly the cost of producing zinc at the Butte & Superior has risen from 4.86 to over 7 cents per pound, an increase of 44%. It will be unpleasant and difficult to revert to the cheaper methods of exploitation when the metal markets relapse.

STOCKS of supplies on the Rand, as at other mines in other parts of the world, have been enlarged on account of the uncertainty of shipping. Thus the value of stores and material held by the mines of the Witwatersrand on July 31, 1916, was £2,600,000, as compared with £700,000 on July 31, 1914—an increase of £1,900,000, or about \$9,500,000. However, the working cost has risen only 16 cents per ton, to \$4.45 per ton, but this, of course, does not include taxation and other expenses omitted in accordance with the pernicious custom obtaining among South African mining companies. The War has caused many of the white employees to serve elsewhere, but the supply of native labor has improved. Another notable consequence of the War is a loss of 12 cents per ounce in the realizable value of the gold, this being due to the extra cost of freight and insurance.

SUPPOSED indefinite persistence of ore in depth suits the promoter and has been used by him many times to enhance the valuation of mines. When the Shamva orebody was uncovered in Rhodesia the promoters of the company formed to exploit it were never careful to limit their expectations, so that the mine was much overvalued and large blocks of shares were sold to an unsophisticated public. Some people think that that is why mines and public were created. We think otherwise. The basic purpose of mining is to make money out of mines, not out of human gullibility. Now, when the mischief has been done, the directors give their shareholders a report by Mr. G. S. Corstorphine in which that distinguished South African geologist states that "the limits as shown by the present workings give practically its [the orebody's] entire mass." He states that the so-called fault, which suggested the hope of finding another

part of the orebody beyond the dislocation, is only a fracture that demarcates the ore. Several years ago the evidence indicated the gradual constriction of the orebody and the probable diminution of ore in depth, but those in control pooch-pooched the inference. They have to acknowledge it now, after the public has been victimized by the earlier optimistic reports.

WHILE the Mexican Constitutional Congress was convening at Queretaro and Señor Carranza was presenting his Magna Carta to the delegates, Pancho Villa was pursuing Trevino's army out of Chihuahua. The *de facto* Government of Mexico has been stultified by its inability to come to the rescue of Chihuahua when attacked by two or three thousand men. The capture of the principal town in the North proves the smallness of Carranza's military resources and exposes his inability to overcome organized revolt. Washington played its money on the wrong horse. The Mexican position is summarized succinctly by that humorous philosopher *Life*: "Next most welcome to having General Carranza's government agree with ours, with suitable results, would be to have it disagree, with appropriate consequences. What we don't want is to have Mexican matters muddle along any further the way they have been going." In short, watchful waiting is wearisome.

REFORM of the mining law was made the subject of a questionnaire, or referendum, to members of the Mining and Metallurgical Society of America and also to 14 other organizations. Of the latter, only one, the California Metal Producers Association, sent the answers of individual members, while two—the Northwest Mining Association and the Nevada Mine Operators Association—voted as units. The expression of opinion was strongly in favor of an abandonment of 'discovery' as a preliminary to location, and the extra-lateral right was condemned almost unanimously, but a number of other reforms, such as the limitation in the number of claims allowed to a locator and the substitution of money payment in lieu of assessment work, found no general support. We cannot see that the referendum is anything more than a parlor game among a number of pleasant people, most of whose opinions might be anticipated by a detached spectator. A society with a membership of 250, of whom only 123 took part in the referendum, is not in a position to reform the mining laws of the United States—laws that affect so many people whom they do not represent. In short, our friends take themselves too seriously. The profession contains at least 2500 men fit to be members in a professional society such as the Mining and Metallurgical; at present the active part of the society consists of a dozen clever and interesting gentlemen living in New York. They are exponents of the best thought and the highest ideals of our profession, but they have no mandate to speak for the mining profession of the United States, much less the mining population of the country. In scanning the replies to this referendum we find one that would, we think, find wide support

among thoughtful men: "My belief is that the old law has already done practically all the damage that it will ever do, and what damage might follow from leaving the law as it is would not be a circumstance to the confusion that would arise from enacting a new law."

STATE mining may be an academic subject in this country as yet, but it is one that is on the horizon, for State ownership of other kinds of industry has been suggested from time to time. In South Africa the subject is a burning question, on which opinions are being elicited by a commission appointed by the Government. We note that one of the witnesses recently catechized by the South African State Mining Commission is Sir George Albu, a mine operator and financier of recognized ability and sagacity. He was frankly against the idea of the State operating mines on the Rand. "Mining," he said, "is always risky, and under State control there would be a tendency to employ political adherents"—of course, like the State Mineralogist's office, in California, for example. He proceeded to say: "A tendency exists to ignore amortization. Without speculation there would be no mining. Propagandists ignore the difficulties and dangers attendant upon mining." Warning to his subject, Sir George referred to the "absolute rot" that had been said about the mines of the Rand; the world had been hypnotized with extreme statements about inexhaustible riches; the awakening had long since taken place. Finally, he asserted that "few individuals distinct from the general public favor State mining." For this abstract of his testimony we are indebted to the *Financial Times*, London. The "absolute rot" that has been talked concerning the Rand is due to the fact that the local papers at Johannesburg and some others in London are subsidized, directly or indirectly, by the financial houses, and also to the fact that some engineers sell not their professional services only but their souls also to their employers.

Porphyry

In our issue of November 18 Mr. W. N. Thayer made a protest against the use of the term 'porphyries' as applied to a group of low-grade big-scale copper mines. His objection is well taken. Among the mines to which he refers are several, such as the Inspiration, Miami, and Ray, in which the principal ore is chalcocite, not in porphyry, but in schist. Indeed the characteristic that the ore deposits mined by the Utah Copper and Nevada Consolidated companies share with the orebodies in the Inspiration and Miami mines is not a similar lode-rock, or matrix, but the dissemination of small particles of chalcocite. Therefore the term 'disseminated copper' mines is preferable.

To the miner 'porphyry' is a word rich in associations; it is resonant with suggestions of mineral wealth. The prospector and the digger have appropriated the term for their own and widened its meaning despite the protest of the petrographer. The word 'porphyry' is

of Greek origin and means purple. The Romans gave the name *porphyrites lapis*, or purple stone, to the rock that they obtained from their quarries at Djebel Dokhan in Egypt. This was the *porfido rosso antico*, or red antique porphyry, of the Italians. According to Zirkel this original 'porphyry' had a beautiful blood-red ground-mass speckled with small snow-white and rose-red crystals of feldspar, the feldspar being a plagioclase accompanied by needles of black hornblende and small crystals of specular iron. Throughout the rock there ran a network of minute veins of accessory quartz. The ground-mass itself was homogeneous, so that no crystals of quartz or feldspar were distinguishable. Such a rock today would be called a 'porphyrite,' and Pliny indeed speaks of the "*porphyrites in Egypto*." Agricola mentions the fact that the columns in the mosque of St. Sophia at Constantinople are made of this same 'porphyry.' Owing to the appearance of this rock the original significance of the term 'porphyry,' indicating purple color, was transferred to the spotted character due to the presence of noticeable crystals in a dense matrix or ground-mass, causing what we now call 'porphyritic' structure.

It may be interesting to recall the fact, related by Vandam in 'An Englishman in Paris,' that it was intended to cut Napoleon's tomb from the ancient porphyry. Guizot got into trouble over the matter in the following way: Visconti, the architect of the Napoleonic monument at that time being erected at the Invalides, wanted the sarcophagus to be made of red porphyry. Guizot acquiesced. It was found, however, that the old Egyptian quarries were exhausted. Inquiries were then made in the Vosges, in the Pyrenees, and elsewhere, for similar stone, but without success, and the idea was about to be abandoned when it was learned at the Ministry of the Interior that this variety of ornamental stone existed in a quarry on the bank of Lake Onega, in north-western Russia. The quarry, however, belonged to the Crown and could not be worked without the payment of a tax. On becoming acquainted with the purpose of the French engineers that had charge of the affair, the Czar Nicholas remitted this tax, about 6000 francs. Although the French paid for the entire cost of the excavating, cutting, and transport of the stone—over 200,000 francs—yet the report was circulated that "Russia had made France a present of the tomb of Napoleon," much to the annoyance of Guizot and the other French ministers.

In designating rocks of this class the ancients restricted the term 'porphyry' to the red variety, thereby recognizing the etymology of the word. Rocks of the same kind, but of other colors, were, according to Quenstadt, called indiscriminately *marmor*, or marble. To the modern petrographer a 'porphyry' is an igneous rock having a homogeneous groundmass that encloses distinct crystals, such as quartz, feldspar, hornblende, or some other mineral, according to which it becomes a 'quartz porphyry,' a 'feldspar porphyry,' an 'augite porphyry,' a 'hornblende porphyry,' and so on. The groundmass may be micro-crystalline or it may be glassy,

and the rock accordingly may be, for instance, a 'granite porphyry' on the one hand or a 'rhyolite porphyry' on the other. In short, the word 'porphyry' is not the name of a particular rock, but an adjectival noun referring to a particular structure or habit, not to the mineral composition. It is more correct therefore to speak of a 'porphyritic rhyolite' than a 'rhyolite porphyry.' According to the German petrographers, the porphyries having a glassy groundmass belong to the newer eruptives, just as those having a micro-crystalline base are supposed to be of more ancient origin. The propriety of this distinction is questioned by many petrographers in the United States and in England. The term 'porphyrite' was confined by Rosenbusch and other German authorities to the pre-Tertiary plagioclase-hornblende group of porphyries, such as diorite-porphyry.

To the Western miner 'porphyry' means an eruptive rock—whether occurring in sheets, masses, or dikes—that is distinguished from granite by its finer grain, and from limestone, and quartzite, or other metamorphic rocks by its fracture. The 'bird's-eye porphyry' of Leadville, which Emmons labeled 'quartz felsite,' is to the Western prospector a type of rocks of this kind. Ignorant as he may be of scientific nomenclature, the average miner has a clear idea concerning the association of certain rocks with deposits of ore, and the knowledge of that association affords him often a serviceable guide in his work of exploration. The 'porphyry' of Colorado is usually a quartz-andesite, the old name of which was 'dacite,' because it prevails in the old Roman province of Dacia, now Transylvania, when it is not part of Germany or Rumania. In California the term 'greenstone' is used in a similar loose way and is likewise associated with ore deposits, particularly gold-bearing quartz veins. In the foot-hill region 'greenstone' is usually either diabase or diorite; and it is to be noted that the speckled or true porphyritic habit of the porphyries in Colorado is not as marked a characteristic of the greenstones in California. Therefore the term has become a misnomer. Much more so, however, is the description of copper mines in schist as 'porphyries.' We hope that technical men will abstain from such blundering usage.

Free Trade in Knowledge

In this issue we publish an interview that serves to summarize the professional career of a supremely useful and public-spirited citizen. Few men are better known or have made more friends in an honorable way than Edward Payson Mathewson. The reasons for it appear in the interview, for no man can be catechized intelligently for a couple of hours without disclosing the main-springs of his action. To us it seems that the metallurgist so long associated with the successful management of the Anaconda works is particularly the exponent of free trade in knowledge, of the open shop in experience, and of the helping hand to the young men of the profession. All of this argues a generosity of mind that is far more admirable than the giving of money or the

endowment of libraries. In the 14 years spent at Anaconda, Mr. Mathewson gave mental hospitality to thousands of technologists from every civilized country in the world, showing willingness not only to allow properly accredited visitors to see the splendid establishment that he directed, but also to give them hints and suggestions that have proved fruitful in many smelters far from Montana. And he did this without allowing any trespass on the property rights of the company whose representative he was; at times reticence—even secrecy—may be required by the exigencies of business, and he knew when those times had arrived, and also when they expired, but it is remarkable that he was able to reconcile his duty to the company with his hospitality to visitors so that the latter forgot the small withholding in the large enlightenment. Another sagacious Canadian, Mr. James Douglas, the Bryce of mining, long ago exposed the stupidity of secrecy in the arts, and himself adopted the open-handed policy, believing it to be best for all concerned. We note Mr. Mathewson's reference to the fact that when the Guggenheims made their big consolidation of smelters, in 1899, it was the secret plants that were found so inefficient that they were put out of business. And we can say, what he naturally forebore from suggesting, that the establishments conspicuous for willingness to give information are exactly the ones that have prospered exceedingly, both in a technical and in a financial sense. Of course, a metallurgical secret is an absurdity, for operations cannot be conducted on a big scale for any length of time without their rationale becoming known to so many men as to render it impossible to withhold the essential knowledge within the smelter-yard. Any enterprising competitor or persistently curious investigator can ascertain the facts if he has sufficient cause for doing so. Secrecy usually indicates meanness of spirit or a desire to cloak ineptitude. The secrets of technology are sometimes only blunders.

But Anaconda under Mr. Mathewson's régime, as it is likely to be under the charge of his able successor, Mr. Frederick Laist, stands for something even finer; it has been a post-graduate school for young metallurgists. We envy Mr. Mathewson nothing so much as the gratitude and respect that goes out to him from scores of technicians, some of them now distinguished metallurgists, on account of the chances he gave them in the years of their apprenticeship. To be able to afford such training is one of the distinctions of which a big reduction works may well be proud. Anaconda has produced something more valuable than copper, than zinc, even than the precious metals. It has made men and the leaders of men. The interview is rich in hints to the young fellows; not to be afraid to tackle any job that is offered, to train themselves in preparation for an emergency, to make records of technical observations, to write technical articles when the necessary material has been collected, to learn to use the English language effectively, to be not afraid to soil their hands with work, yet not to spend too much of their early days at manual labor, to make the acquaintance of the older men, and to not neglect their social duties.

The Playa Blanca episode was the most crucial in Mr. Mathewson's career. It must please our readers to see how men of real bigness of spirit triumph over disaster and live to present their compliments to those that did them an injustice. Mr. Channing has related how he was dismissed by the Bourbons at the Calumet & Hecla, and how he lived to be asked by that company for his technical advice in later years; Mr. Mathewson tells us how he was 'fired' by the Guggenheims at a time when they practically controlled all the lead smelters of the country. As the smelting of lead ores was his specialty, the dismissal seemed calamitous at the time it happened. Time has proved that he was right and that the Guggenheim directorate was wrong, and it has demonstrated also how a man of real capacity cannot be kept down by anybody. From lead smelting, Mr. Mathewson went to copper smelting, in which he achieved an equal specialization, and now, as if to round his career by attacking fresh problems, he takes charge of a big nickel enterprise. We can readily understand how gratifying it must be to him that he has been selected for work so interesting and so important as the British governmental exploitation of the nickel industry in Canada.

The labor question is one that every wide-eyed man must face. Knowledge of humankind is at least as important as that of the metals. Our readers will appreciate the spirit animating Mr. Mathewson's remarks on the relation of employer to employee. Of course, he has placed his index finger on one of the fundamental weaknesses of the big corporation, namely, the dehumanizing of the administration. You can make machinery automatic—or very nearly so—but the complex play of the human relationship will slip a cog if there is no personal contact between the workman and the manager. How well Mr. Mathewson succeeded not only in his duties as an engineer, but also in his obligations as a free citizen in a civilized community is shown by the demonstration that was made when he left Anaconda on October 16. From the local musical organizations that he had encouraged, to the children for whom he had created playgrounds, from the technical men on his staff whose friendship he had won, to the people of the town whose goodwill he had gained—from all of these he obtained a regretful farewell and an enthusiastic godspeed that must have thrilled him to the very core of his being. It was a demonstration of which not only he and his family, but the profession whom he so worthily represents, may well be proud. Other men have been given gold cups and paintings, but there are sentiments that no organized testimonial can express. "For his welfare work in the Town; for his good work in the County and State; for the many things he has done to make this a pleasanter and better place to live, we owe him a debt of gratitude that we cannot repay, and we assure him his name will always be synonymous with good citizenship in this State." Thus said Mr. Laist in an eloquent speech at a farewell dinner. To have "a name synonymous with good citizenship" that is worth more than much refined copper. Young man that reads this: go thou and do likewise.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Grinding Mills at the Inspiration

The Editor:

Sir—I am pleased to note your prompt correction of the unfortunate error which seemed to reverse the meaning of my statement in regard to the experience of the Inspiration Consolidated Copper Co. in their test-mill work using both the Hardinge and Marcy type of grinding mills. I note also that this 'slip of the types' brought a prompt remonstrance from Mr. Hardinge, indicating that the controversy over the form of these popular simplified grinders still lives.

To those who recall the effective advertising program adopted by the Hardinge Conical Mill Co. immediately after they had sold the Hardinge patent rights for Arizona to the Inspiration company it doubtless was quite a surprise and somewhat of a shock to learn that after extensive experiments with both the Hardinge and Marcy machines, the Inspiration company had finally adopted the latter for the extensive grinding equipment required in their new mill. The Hardinge machine was not condemned; its final trial was simply deferred. Those who are familiar with all the circumstances connected with this decision to use the Marcy machine do not criticize the wisdom of it, but there is little doubt that the course pursued left the impression on the minds of the milling public generally that the Marcy type of ball-mill had won in a fair competition with the Hardinge type of ball-mill, and it was in order to correct, in some measure, this erroneous belief that I referred to the matter in the technical discussion you quoted.

Except for determining the comparative value of the material used in the grinding media, it is manifestly unfair to compare the work of a machine using flint pebbles with one using iron or steel grinding media. Mr. Blickensderfer fell into the error of making such a comparison in his paper entitled 'Comparative Test of the Marathon, Chilean, and Hardinge Mills,' which was read at the Globe session of the A. I. M. E. meeting in Arizona, in which he assumed that the work of a Hardinge mill carrying flint pebbles and lined with pebbles should be as good per unit of power as that of a Marathon mill lined with white iron and carrying steel rods as grinding media.

More experiments, to determine the best form of these various types of grinders, and also to get at the facts in regard to the best material, size, shape, etc., to use as grinding media in them, are probably being made in the

South-west than anywhere else at present. The various companies in this region that are interested in the developments are inclined to co-operate with each other in every way, to the end that the good points of each grinder may become a matter of common knowledge among them. The Inspiration company may be considered as temporarily favoring the Marcy mill, the Miami company the Hardinge, and the Phelps-Dodge company the Marathon; but the prejudices of none of them is fixed. That they are still open to conviction and anxious for the truth is made evident by the money they are putting into the installations noted below.

The present Inspiration mill is completely equipped with Marcy mills and is now handling about 16,000 tons of ore per day. Additional sections are being added to the plant and in one of these sections two 8-ft. by 36-in. Hardinge ball-mills, especially designed to meet the Marcy type in a fair competition, will be installed. I understand that the machines will be placed tandem and the first one of the series will receive exactly the same feed as that fed to the adjacent Marcy machines. Its product will go to a mechanical classifier, which determines, through an overflow arrangement, the final degree of comminution; the second mill in the series will work in closed circuit with this classifier, thereby finishing the work to the standard for the district, namely, 1 to 3% plus 48-mesh. The first mill will carry large balls believed to be best suited for reducing the coarse feed, and the second one will carry smaller balls, which are thought to be the best adapted for the final reduction. By using this combination Mr. Hardinge hopes materially to reduce the power required to grind a unit of ore, and otherwise to make a good showing for his machines. The competition will be direct and fair; opportunity for measuring power, weighing input, etc., will be ideal, and the merits of the competing mills will be clearly brought out.

In a neighboring plant the Miami company has been using for some time a full equipment of 8-ft. Hardinge mills in its fine-grinding department. These were installed as pebble-mills but have since been adapted as much as possible to carry steel balls. The result, however, has not been as good as could be expected with machines especially designed to carry 'balls.' This company is the pioneer in the use of the Hardinge machine in the district and has been very favorably inclined toward this type and believes that its use results in the saving of considerable power. The Miami company now proposes to use 8-ft. by 28-in. specially designed Hardinge ball-mills in groups of three. The run-of-mine

will be reduced in crushers to pass a $\frac{1}{4}$ -in. hole and in this condition will be fed to the first one of the Hardinge mills, which will discharge to classifiers, the overflow of which will be finished material, and the coarser sand will be split at the classifiers into two Hardinge ball-mills carrying somewhat smaller balls and adapted to finish the grinding. The last two mills will work in closed circuit with the classifiers and this arrangement will make it possible for the company, besides getting finer grinding than it formerly obtained, to increase considerably the capacity of each section of the plant.

Thus in the Inspiration mill we shall have direct comparison between the work of real Hardinge ball-mills and the standard type of Marcy mill. At the Miami concentrator we shall have real Hardinge ball-mills arranged in what should be an ideal combination for getting the best results out of them. In both cases the grinders will handle ore from practically the same orebody, having the same degree of crushability, and the results obtained should be important and quite conclusive; and these will be the first conclusive results to be obtained, for the reason that this will be the first time these two types of mills have been operated in a proper and fair competition with each other.

During the late trip of the A. I. M. E. party through the district, both of these companies gave out detailed figures as to the results being obtained in their plants. At the Inspiration mill, it is notable that in grinding from $1\frac{1}{2}$ -in. size to 2.9% plus 48-mesh in fine-grinding Marcy mill-sets (including also the operation of the classifiers and belt-conveyor for the feed to the mills) the power used was 9.86 kw.-hours per ton ground; and when the power required for preparing the feed from run-of-mine to $1\frac{1}{2}$ -in. is included, the total amounts to 10.27 kw.-hr. per ton. At the Miami mill the power used for crushing and grinding was given as 7.86 kw.-hr. per ton; but since Miami does not grind all of its tailing to pass a 48-mesh screen, the mills there have not done as much work. The present tailing of the Miami mill contains 11.5% plus 48-mesh, as compared with 2.9% plus 48 found in the tailing of the Inspiration mill, and this difference may account for the difference in power reported.

I understand that the larger Marathon mills being operated by the Detroit Copper Mining Co. at Morenci, Arizona, and the Burro Mountain Copper Co. at Tyrone, New Mexico, have given excellent results as to output per unit of power, and that they are pleased with them. There has been some little mechanical difficulty that has been overcome. These mills have not been run in competition with ball mill or tube mill grinders using iron grinding media. It is significant to note that the Burro Mountain company is preparing to try 'manganoid' balls in a Marathon mill. I do not think that they expect to increase capacity or conserve power by using balls in stead of rods, but I understand that they are interested in proving whether ball ground product is better prepared for flotation separation than rod-ground product and incidentally the results of this trial will be interest-

ing as bearing on the general subject of what is the best form to use.

The New Cornelia Copper Co. is installing a fine-crushing plant using Symons vertical disc-crushers for reducing from $3\frac{1}{2}$ -in. cube to $\frac{1}{4}$ -in. size in two stages at the rate of 400 tons per hour. This type of machine is capable of crushing from 4 to $\frac{1}{4}$ in. in a single stage, but it is thought that power will be conserved and a more desirable arrangement result from dividing the work between three machines per unit, working in two-stage reduction similar to the Miami plan for the use of the Hardinge mill. The Symons machines were designed especially for the work and should set up a new mile-post in crushing-work of this character.

All of these interesting experiments promise to come to fruition early next year and should add materially to our knowledge of crushing and grinding as practised in metal mining.

El Paso, November 21.

DAVID COLE.

Constructive Aid for the Prospector

The Editor:

Sir—The fact is patent, without referring to statistics, that the prospector finds a more attractive field for his endeavor in Canada and other foreign countries than his old stamping-ground, the United States and Alaska. Since the prospector is the fundamental operator of the mining industry, his important relation should be carefully analyzed and the conditions under which he operates well established. The activity of the prospector in the field is a well known index to the activity of mining and any interference with his freedom of operation is directly reflected in a retardation of the industry.

The Federal government, through its Bureau of Mines, can do nothing more useful than study the reasons for the rapid migration of the prospector to foreign fields and remove the causes of it by recommendations to Congress. Pursuant to a better understanding of this subject, it is well to cite a number of the reasons that are most destructive to the occupation of the prospector in the United States and Alaska, as the prospector sees them.

The inborn patriotism of the American is so strong that it is a hardship for him to leave this country for any economic reason, but when he does go into foreign parts, he feels that his own Government should care for his welfare at least as much as the government of the country to which he goes. His position in this matter is sane. Often the United States, for lack of a system of aid to the prospector, not only loses the result of individual enterprise but also a citizen.

To trace this feeling generally that the Government is not protecting but rather hampering the prospector's efforts, it is necessary to go back to 1906-1907 when the land-fraud cases in the North-West and Alaska forced the President to withdraw thousands of acres of public land and place it in reserve to await more specific classi-

fication before re-opening it for entry. At about the same time the conservation idea was sown broadcast without qualification. Like most reforms, the conservation movement was born in theory and since has been developing to meet more practical demands. The theoretical stage was marked by the grossest economic waste of our natural resources, while the more recent constructive conservation recognizes the necessity for developing and using our natural resources. While this movement in the United States started because of high-handed and dishonest land and timber locators, the Alaskan withdrawals resulted from fraudulent coal locations. To the prospector a speculative element was introduced into the title to his holdings. The capitalist backing the prospector soon withdrew his aid on the ground that the title in fee might not be forthcoming as security for his investment. It remained for the Department of the Interior to dispel this idea of uncertainty. The constructive work of the present Department of the Interior began to be felt through the expediting of titles (by clipping much red tape) and through legislation.

The re-opening of vast areas in the United States and Alaska to entry; the passage of the Alaska Railroad and Coal-Leasing bills, marked the first steps in permitting the development of our natural resources after a period of lethargy during which thousands of prospectors were forced to change their field of operation.

The United States Geological Survey has won the public confidence in matters pertaining to land classification. This is due largely to the fact that most capable geologists are selected to advise in such important business. The classification of the natural resources on the public domain, which responsibility Congress long since called upon the Geological Survey to assume, should be rigorously sustained by the issuance of the corresponding land-titles by the U. S. Land-Office. Inasmuch as the funds available are not sufficient to enable the U. S. Geological Survey to keep pace with the public demand for land classification, Congress should recognize the need for increasing this appropriation to an amount commensurate with the public demands, in order not to further block the development of our natural resources. The prospector is vitally concerned in this matter of land classification, and unless the classification keeps pace with his activities, a delay is introduced that is inimical to his best interests.

Many foreign countries have for some time been extending aid to the prospector, both educational and personal. Therefore, in order to complete any system for the help of the prospector, it will be necessary to establish this personal relationship between the prospector and the Government.

From the successful experience of the Bureau of Mines in educating the coal miner in matters of safety, the inference may be drawn that no less success would be attained in extending personal aid to the prospector, but with a different purpose. This favorable result emphasizes the fact that the most successful government is the one which anticipates the needs of those upon whom it depends for support.

This personal aid from a government to the prospector can be no better illustrated than by recounting an experience on the Queen Charlotte islands, off the coast of British Columbia, in 1908. In the month of February, I landed at Jedway, on Moresby island, amid the excitement of a copper discovery. On the same boat was shipped, by the Government, a portable house for the Mining Recorder, a complete set of record books, etc., a portable prison, a Mining Recorder, and a force of men to build trails, fully equipped and provisioned. While many prospectors went in, there was no confusion; individual rights were clearly defined and protected; and the prospectors had every opportunity to devote their time to prospecting rather than to the building of trails. Shortly after came the technical branch of the Government service to counsel and advise the prospector and to publish authentic reports, which were followed by the capitalist's engineer, and the financial assistance to the prospector who had developed a likely prospect. The mining industry based upon so sound a premise of Federal action is bound to be progressive and flourish to the utmost. This is an excellent investment of public funds, judging from the results. One should not wonder why so many prospectors go to Canada when they know that this vital assistance will be rendered.

During the winter months a course of practical lectures is given for the benefit of the Canadian prospector. From these lectures on field mineralogy, methods of mining and milling, and the interpretation of mining law, the prospector gains a grasp of the larger problems of the industry in which he is engaged. He is also better able to estimate his position with respect to capital when he is about to close a deal for his prospect.

The U. S. Bureau of Mines is naturally adapted and organized to assume these functions of personal aid to the prospector. There is no need more pressing than this constructive program. Congress must fully recognize the responsibility of our Government to control the future of a great industry by creating a sound foundation for further progress. It will not require a big appropriation because the means of accomplishment have been partly provided in the establishment of experiment stations throughout the United States and Alaska. In fact, to expand the activities of the Bureau of Mines so as to include this personal service would be to return more dividends from an investment already made.

Now that the general activity of mining is so much improved over past years, there would seem to be a most favorable opportunity to start this work. For the same reason there also appears a still greater need for directing and conserving the efforts of the prospector.

H. N. LAWRIE.

Portland, Oregon, November 15.

MAGNESIAN LIMESTONE, though not preferred by smelters, has been used successfully as a flux. Long campaigns were carried on at the Deadwood & Delaware smelter, at Deadwood, South Dakota, by Dr. Franklin R. Carpenter, when only magnesian limestone was available as flux.

From Precipitate to Bullion

By R. R. Bryan

One of the disagreeable and unsatisfactory performances in a small cyanide plant, employing zinc-dust as a precipitant and treating gold ore, is the handling of the 'clean-up.' It is aggravating that when the precious metal has been concentrated to the degree represented by a precipitate, that still further concentration and refining to a marketable product should require such unwieldy, laborious, and trying operations. In large plants the handling of quantities minimizes some of the difficulties incidental to small plants, but even then it would seem that there is room for improvement over the present cumbersome smelting methods.

The Tavener lead-smelting method, with modifications, is most used in large plants but it entails a tie-up of values and a re-treatment of products that is prohibitive to the small plant.

The method of refining herein described was developed after several months of experimenting and has proved an improvement over the method formerly in use.

Since the difficulties of refining are greatly reduced when treating higher-grade precipitates, it is of first importance to direct attention to such a regulation of the conditions governing precipitation as will produce the highest grade of precipitate possible without increasing the cost or disturbing other essential factors. The way in which this is accomplished is known generally but an outline of the procedure may help those not so familiar with cyanidation. The conditions favoring the making of the best precipitate for refining are:

(1) A pregnant solution free from suspended matter. A clarifying press or similar means is well worth using and there should be no excuse for suspended matter in solution.

(2) A pregnant solution of maximum value per ton. This will depend on other plant conditions and must be determined for each plant accordingly.

(3) Use of the least amount of zinc dust that will give the required barren solution. This will depend on the conditions and requirements of the plant.

(4) A constant cyanide and alkali strength of the solution precipitated. This can always be obtained by careful watching and regulation of the pregnant solution.

Having obtained the best grade of precipitate that the plant can yield economically, its value may be from \$10 to \$60 per pound in gold, the next step is the acid treatment, by which the value of the precipitate is increased \$50 to \$150 per pound.

A decided difference of opinion exists as to the efficiency of sulphuric acid treatment, especially in the small plant. It is undisputed that it removes a large quantity of zinc at a low cost and with much less trouble and loss than can be obtained by the fire method. It is also true

that it introduces sulphur, which, in the subsequent melting, tends to form matte and produces a product whose treatment is generally more destructive to the graphite pot. Prolonged washing reduces this difficulty to a minimum but does not remove it. The use of acids other than sulphuric seems to be regarded with mistrust, probably on account of the greater danger of putting metal into solution and the greater cost and discomfort.

Whether acid treatment be adopted, or not, the refining operations have one common source of difficulty and that is the use of the graphite crucible. This kind of crucible was used originally for the melting (not refining) of a relatively pure metal. It has come to the refining of precipitate through its use in melting the precious metals resulting from retorting and its use in the mints. The graphite crucible is not adapted to withstand the fluxing of metallic impurities nor the corrosive action of slags high in metallic oxides or of oxidizing agents introduced to remove matte or base metal. This crucible introduces a condition that is essentially reducing whereas the operation of refining requires a condition that is essentially oxidizing. The metallic oxides formed in the pot readily attack the graphite and are reduced to the metallic state, joining the precious metals. Some metallic zinc is volatilized and part of this will burn to oxide before escaping from the pot and again react with the graphite, being reduced again to metallic zinc, all of which corrodes the graphite pot and defeats the object of refining. A furnace of the tilting reverberatory type with basic lining should be well adapted to the refining of precipitate, as it would permit the use of oxidizers and the formation of a basic slag high in metallic oxides.

The sulphuric acid treatment was selected because it removed a large quantity of base metal and, in spite of the difficulty introduced by sulphur, made the process more efficient and economical.

The acid-treated precipitate is filtered, washed, and partly dried, enough moisture being left to prevent dusting. Fluxing is as follows:

Precipitate	100 parts
Old assay-slag	75 to 125 "
Iron turnings.....	1 to 6 "

The slag is a good glassy slag high in litharge and borax. The melt proceeds rapidly with only slight boiling and the temperature is held high at the last until the dense yellow fumes have subsided. The pot is then turned down and the slag skimmed to the surface of the matte, with care not to skim so close as to get any matte or metal into the first slag, which is a finished slag. The cover must be turned back for this operation and the pot turned down. At this point the metal is usually about

250 to 300 fine doré. After the first finished slag is removed the surface of the matte is kept clean by raking the scum to the side of the pot as rapidly as it is formed. The rim of contact between the surface of matte or slag and the pot is kept fettled with silex or other silicious material to prevent corrosion. As the charge cools the oxidation is assisted by sprinkling nitre over the surface, raking it to one side as soon as its action ceases and adding fresh nitre. It may become necessary to remove some of this skimmed material from the pot to allow more room. In this case the material removed is kept separate and returned to the pot when turned back for re-heating. Before the metal becomes cool enough to solidify, borax glass, nitre, and silex are stirred into it with a rod until it is pasty. The furnace is then turned back and heated

A TILTING MELTING-FURNACE.

The furnace as illustrated above may be fired by gas or gasoline. It rests on trunnions, and can be tilted through more than 90° by means of a crank, thus discharging the contents of the crucible, and relieving the attendant from exposure to heat. The burner is fastened rigidly to the pipeline, and must be shut-off before the furnace is tilted.

again to a high heat, the slag skimmed off as finished slag, and operation repeated as outlined above. The final destruction of matte will be indicated by the cessation of the dense yellow fumes upon sprinkling with nitre and by the general appearance of the surface. As long as much zinc remains in the metal, oxidation will be slow and the surface will be continually freezing with a scum. The process of oxidation and removal of resulting products followed by stirring-in borax, nitre, and silex is continued until the desired degree of fineness is obtained, as determined by taking a dip-sample and testing with touch-stone and needles. Each cycle of operations will require about 1½ hours and will remove about 40 oz. of base metal in a No. 100 graphite crucible.

The question then arises, to what extent is it profitable to refine bullion for the Mint? Before attempting to answer this, it will be well to consider the table of charges at the Mints and Assay-Offices of the United States. The latest of these schedules went into effect on April 15, 1916. A brief exposition of that part of this

Table of Charges which is of interest to one marketing gold bullion will be given.

- (A) Bullion containing over 800 thousandths base will be declined.
- (B) When bullion is so impure that the loss in weight in melting exceeds 25%, a charge in addition to the regular charge is made.
- (C) Bullion that does not give concordant assays on the first dip may be given an extra charge for re-melting and treatment, and if the second dip fails to give concordant assays the bullion will be refused.
- (D) The regular charges are three in number, as follows:

1. MELTING CHARGE. Equal to \$1 each 1000 oz. or fraction thereof as determined from the weight of bullion after melting.

2. PARTING AND REFINING CHARGE. This is the main item of the charges and depends upon the fineness of the gold and the fineness of the doré. From the following the charges per ounce of weight after melting for parting and refining can be determined for each fineness of gold and doré.

Doré fine	Gold fine				
	1-250	250½-500	500½-949½	950-991½	992-1000
	Charge per ounce weight after melting—				
200-299	\$0.08	\$0.09
300-399	0.07	0.08
400-499	0.06	0.07
500-599	0.05	0.06	\$0.04
600-699	0.04	0.05	0.04
700-799	0.03	0.04	0.04
800-899	0.02	0.03	0.04
900-969	0.01	0.02	0.04	\$0.04	...
970-1000	0.01	0.02	0.04	0.02	No charge

3. ALLOY CHARGE. Equal to 2.5c. for each ounce of copper required for alloy, as determined by taking one-tenth of the fine weight of gold in the bullion.

From this it will be seen that the parting and refining charge is the only one seriously affected by the refining. Further study of this portion of the charge will reveal some interesting facts relating to the possible reduction in Mint charges by refining. To the mill-man whose bullion will contain some silver but not over one part in four of gold, the study of this table limits itself to the gold fineness ranging from 250.25 to 949.75. Now from 500.25 to 949.75 the rate is a flat 4c. per ounce regardless of the doré, so that refining beyond 500.25 fine gold only results in lessening the Mint charges by 4c. times the ounces of weight lost by the bullion through the removal of base metal. It is quite safe to say that the loss and cost of refining past 500-fine gold for the small plant usually exceeds 4c. per ounce of gross removed, so that from the point of economy the discussion is limited to fineness below 500.25. When fineness drops below 500.25, the rate is dependent upon the doré and the saving effected by refining is not only by a reduction in weight, but also through producing a doré of higher fineness. For this reason, with good manipulation, it is profitable to refine at least to 500.25 fine in gold. As an example, take the following:

	A	B
Weight after melting	500	460
Gold fineness	490	532.6
Silver fineness	95	103.3
Doré fineness	585	635.9
Parting and refining charge per ounce.....	\$ 0.06	\$ 0.04
Parting and refining charge total.....	\$20.00	\$18.40

If the bar *A* were sent to the Mint the parting and refining charges would have been \$30. The bar *B* is obtained by removing 40 oz. of dross; on this the parting and refining charges are only \$18.40, so that the removal of the 40 oz. of dross has decreased the cost of marketing \$11.60 (or 29¢. per ounce of dross), which should be far in excess of the cost and loss in refining this amount. Refining beyond this point only reduces the cost of marketing by 4¢. per ounce of dross removed. When, for the sake of appearance, it seems desirable to produce bars of a greater fineness than 500.25 gold, this may be done and fineness increased to about 800 doré without any considerable increase in the cost and loss of the operation over the saving effected through reduced Mint charges.

Assume a clean-up yielding 100 oz. gold and 25 oz. silver, and assuming that the precious metal loss in smelting is slight, the following table will serve to show the reduction in gross weight and total Mint charges and the reduction in cost of marketing per ounce of base metal removed for each increase of 50 fine doré.

Doré	Gold	Weight, Oz.	Parting and refining		Total cost	—Reduction in—		
			Oz.	Rate		Weight	Cost	Per oz.
200	160	625	\$0.08	\$50.00	\$51.25
250	200	500	0.08	40.00	41.25	125	\$10.00	\$0.08
300	240	417	0.07	29.19	30.14	83	10.81	0.13
350	280	357	0.08	28.56	29.81	60	0.63	0.01
400	320	313	0.07	21.91	23.16	44	6.65	0.15
450	360	278	0.07	19.16	20.71	35	2.45	0.07
500	400	250	0.06	15.00	16.25	28	1.46	0.16
550	440	227	0.06	13.62	14.87	23	1.38	0.06
600	480	208	0.05	10.40	11.65	19	3.22	0.17
650	520	192	0.04	7.68	8.93	16	2.72	0.17
700	560	179	0.04	7.16	8.41	13	0.52	0.04
750	600	167	0.04	6.68	7.93	12	0.48	0.04
800	640	156	0.04	6.24	7.49	11	0.41	0.04
850	680	147	0.04	5.88	7.13	9	0.36	0.04
900	720	139	0.04	5.56	6.81	8	0.32	0.04
950	760	132	0.04	5.28	6.53	7	0.28	0.04
1000	800	125	0.04	5.00	6.25	7	0.28	0.04

It will be noted that in bringing the gold fineness from 210 to 280, which is effected by the removal of 60 oz. of base metal, the cost is only reduced 63¢, or a trifle over 1¢. per ounce of base removed. Let us examine this point more closely. Comparing the charges on this 100 oz. of gold and 25 oz. of silver when in a bar of 250 gold fineness, it will be shown that in the first case the charges would be \$29.25 and in the second \$33.09. Thus, at this particular point the removal of two ounces of base metal has resulted in an increase of Mint charges of \$3.84 or \$1.92 per ounce of base removed. So it seems that this schedule may result in some peculiar charges. At any rate the charges are so moderate that the marketer of bullion should find no cause for complaint although the irregularity may often afford him a chance to save a few dollars by a little refining when the variation is understood.

RAINFALL of Broken Hill, Australia, was 1.13 in. during the half year ended May 31, 1916.

Alloys of Aluminum

Aluminum alloys are receiving more attention because of their usefulness, particularly in aeronautical construction. The copper-aluminum alloy resists atmospheric corrosion well, which appears to be the greatest advantage of adding copper to aluminum. This alloy can be rolled while hot up to a content of 12% copper, though where it is intended to roll the metal 3 or 4% copper is best. For castings, copper to the amount of 10 to 15% may be added to advantage. Nickel acts in much the same way as copper; alloys containing 11 to 12% nickel roll readily when hot, though about 4% is the amount generally added. For castings, 10 to 12% nickel is added. While iron-aluminum alloys possess no particular advantage, aluminum containing up to 2 or 3% iron is not injured by the presence of the iron. It is claimed that the most valuable aluminum alloy thus far made is that produced by the addition of zinc up to 12 or 14%. This alloy possesses about the same ductility as pure aluminum with high tensile strength. Alloy containing 25 to 30% zinc is stronger but is much less ductile. Aluminum-zinc alloys are not suitable for castings. Aluminum-magnesium alloys with the magnesium over 6 to 7% cannot be rolled and shrinkage is least between 3 and 4%. For castings the magnesium content should be between 8 and 12%, if higher the alloy is too brittle. Silicon-aluminum alloy has about the same specific gravity as pure aluminum. The best proportion has been found to be from 5 to 7% silicon for rolled metal and 10 to 12% for castings. With silicon under 8% the alloy suffers less corrosion from water than pure aluminum. Tin-aluminum alloys are valuable and can be rolled cold, but will crack if rolled when hot. These latter alloys resist atmospheric corrosion well, but the elastic properties are seriously affected by the addition of tin. The addition of either lead or bismuth to aluminum has been found to possess no technical advantage. Chromium added to aluminum up to 5 or 6% produces a valuable alloy; one that can be rolled at 500° C. with as much as 4 or 5% chromium, but when the alloy is made with the intention of rolling, not more than 1% should be added, and for casting about 3%. Manganese, up to 5%, can be added and this alloy rolls easily, but the alloy has no advantage over others. Tungsten added to aluminum renders the alloy extremely brittle. Experiments have been made in adding various other elements to aluminum, among them molybdenum, vanadium, titanium, tantalum, and zirconium, but these alloys have been found to possess no particular advantage over the others above mentioned.

COAL consumption in the United States used in heating and cooking is estimated at 1 to 1.5 ton per capita. In 1915 it is stated to have been 1.1 ton. The total consumption of coal for all purposes is about 4.6 tons per capita. The present high and still rising price of coal is charged to the shortage of labor, and of cars for shipment.

E. P. Mathewson, an All-Round Metallurgist

An Interview. By T. A. Rickard

Mr. Mathewson, you are a Canadian?

Yes, I was born at Montreal on October 16, 1864.

Where did you get your early education?

At Montreal, in private schools and the high-school, graduating from McGill University in mining engineering in 1885, as Bachelor of Applied Science.

Was your father connected with mining or metallurgy?

No. He was a wholesale grocer at Montreal, and his father before him.

What made you take to metallurgy?

Intuition, I think. It fascinated me. My first impulse toward metallurgy came when looking at some models of furnaces in the college at McGill. When I entered McGill I did not know what course I was to follow, and went through the first year without making a decision.

What was your first job?

I was a surveyor on the Dominion Geological Survey, surveying lakes in Ontario under Eugene Coste. He was head of the party; A. R. C. Selwyn was head of the Survey at that time; my immediate superior was E. H. Vautelet.

Did you remain with the Survey long?

Just for the summer; then I killed time around my father's establishment during the winter months, and the following spring I decided to go to Colorado. I did not know anyone in Colorado, so I asked my old professor of chemistry, Dr. B. J. Harrington, if he knew of anyone in the West. He referred me to T. Sterry Hunt. Dr. Hunt received me most kindly, at his residence in Montreal, and told me that he knew of one of his former pupils at Yale who was in the smelting business in Colorado, namely, A. W. Geist, and he gave me a letter of introduction to Mr. Geist.

So then you proceeded to Denver?

I met a friend, Tom Drummond, another graduate of McGill, in civil engineering, who was going West to British Columbia. We traveled together as far as Kansas City, where he missed the train, leaving his surveying instruments on board. He wired me to leave them at the Windsor hotel in Denver, which I did. On arrival at Denver, I found there a gentleman by the name of Cushing, who was a Canadian, and who advised me to go to Pueblo as soon as possible, and present my letter

to Mr. Geist, and not be afraid to tackle any job that I might be offered.

That was good advice.

Yes. That's good advice for any young man—always to be prepared to take what is offered, even to the extent of making a small bluff. I took the first train for Pueblo and found Mr. Geist in a receptive mood. It seems that one of his assayers, Ben Sadtler, was leaving him to accept a better position, to take charge of a small furnace at Canyon City, so Mr. Geist told me to report next morning. That was the last day of March 1886. My name went on the payroll of April 1, 1886, but in spite

HOWARD LEAD PRESS AT PERTH AMBOY.

of the date, it has been off the payroll very seldom since. My salary was \$50 per month, 13 hours work on night-shift, and 11 hours on day-shift alternately, in two-week stretches. My partner on the opposite shift was E. N. Engelhardt, now superintendent of the Selby smelter.

The smelter of which you have been speaking was, I take it, that of the Pueblo Smelting & Refining Company.

Yes. A Boston corporation. I remained with that company until March 1897. At the end of nine months I was promoted to the all-day shift, and shortly after was transferred to the laboratory and given over to the tender mercies of the chief chemist, E. C. Engelhardt—no relation to the one previously mentioned. Incidentally, the former is a Russian by birth, and the latter a German. After a few months in the laboratory, owing

to the fact that the chief metallurgist, H. H. Schlapp, left the employ of the company to go to Australia, there was a general move up; Baron de Ropp was made chief metallurgist, my old chum Engelhardt, became his assistant, and shortly afterward the Baron, then 'Tommy' Ropp, left, and Engelhardt became chief metallurgist, and I was promoted to be his assistant. Within a few months de Ropp went to Anaconda to take charge of the lower works there, and sent for Engelhardt to act as his assistant, thereby creating a vacancy, to which I was promoted.

By that time your salary had been increased?

Up to \$150 per month. I made some slight remonstrance with the manager, Foster Nichols, and after some correspondence with the Boston directorate, my salary was increased to \$250 per month, but that included the supervision not only of the lead-silver smelter but the copper department as well, the head of that department, William Foster, having resigned.

What was your copper process?

It was the Crookes process, whereby the matte from the lead blast-furnaces containing a certain amount of copper was desilverized in a series of reverberatory furnaces, in each of which there was a bath of molten lead. After desilverization the matte was given an oxidizing roast, to form what was called 'moss' copper, the name coming from the fact that the metallic copper appeared on the surface of the roasted material in a form resembling moss. This moss copper was then treated in blister-furnaces and the blister put into a refining furnace, to be refined by the old Welsh method.

Can you recall any of the figures of cost in those days?

My recollection is that the cost of producing copper from matte by this process was something like \$40 per ton of matte.

What was the cost of your lead smelting?

In the neighborhood of \$4 per ton of ore.

The smelting was done, I presume, in furnaces of the Piltz type?

No. The furnaces were of the Rachtette type, using coke from Trinidad, mixed occasionally with wood-charcoal. We had water-jackets of cast-iron, and we had two wonderful furnaces, 5 ft. by 8 ft., with water-cooled tuyeres projecting inward six inches on each side. When the ore was free from fine, these furnaces would smelt over 90 tons of charge in a day, which was considered impossible by the fraternity, and doubted by our competitors.

Your ore was mostly from Leadville?

Yes. A little of the copper ore came from Salida. Not much of the ore was treated as strictly copper ore. Some of it came from the San Juan and Clear Creek.

What caused you to move from Pueblo?

In 1897 Ben Guggenheim of M. Guggenheim's Sons, offered me the position of superintendent and metallurgist of the Philadelphia smelter at Pueblo, which had

been built nine years before in conjunction with Ed. Holden, backed by the money of Meyer Guggenheim.

That smelter also was at Pueblo, was it not?

Yes, but I remained there only a short time. I had hardly been appointed when Ben Guggenheim asked me to select my successor, and prepare to go to Perth Amboy to manage their lead and copper refinery at that point. I selected R. D. Rhodes, of Leadville, and we made the necessary arrangements for him to take my place. Three months after my appointment as superintendent of the Philadelphia smelter, I was moved to Perth Amboy.

Did the Philadelphia smelter present any remarkable features?

It was considered a large smelter at that time, and the bedding system—the mixing of the ores in beds—was very carefully done by hand, from tram-ears, so that the charge was fairly uniform on the furnace. They had external crucibles and other fancy stuff when the plant was first started, but these innovations were discarded in favor of standard practice.

You found your new post at Perth Amboy interesting?

Yes. This plant was a large lead and silver refinery, for its day, and had the Möbius method for parting gold and silver. This was an electrolytic method, the silver crystals being deposited either on silver belts or silver plates from a nitric acid solution, while the gold was collected as a mud in canvas bags, the anodes being in the bags themselves. We built some of the largest lead-refining furnaces in existence at that time. They were capable of holding 100 tons of lead at a charge. They have furnaces two or three times as big now, at the same plant.

How long did you remain at Perth Amboy?

I remained there until September of 1897, when I was sent by M. Guggenheim's Sons to Monterrey, Mexico, to succeed the late O. H. Hahn, superintendent and metallurgist of a lead plant there. We treated oxidized ores from the Santa Eulalia, Santa Barbara, Angangueo, and Catoree districts in northern Mexico.

Was your practice remarkable in any way?

One notable feature of the plant was the use of gas-producers for firing the roasters. We made our gas from Coahuila coal, otherwise we would have had to import coal from the United States. The limestone was all hauled from Topo Chico, a distance of a few miles, by ox-cart.

You found it pleasant to be in Mexico?

It was pleasant so far as the climate was concerned, but the labor conditions were peculiar. At that time, on the least sign of rain in the afternoon, the night-shift would fail to show up. We would then send our trusted watchman to scour the town and round up as many Mexicans as he could, and we would put them to work, but every evening we had to count noses to see how many furnaces could be run through the night. Another peculiar feature of the labor at that time was the utter

indifference of the Mexican laborer to the company's interest. If a tap-hole broke out and the hot slag ran over the floor, instead of endeavoring to stop it, the peons would dance around the hot slag like a lot of wild Indians in a sun-dance until the furnace emptied herself.

How long did you remain at Monterrey?

Eight months. I was married in 1890 to Miss Aliee Barry of Montreal and by this time I had a family of two children. My wife and family remained in Montreal while I was in Mexico. I left Monterrey because M. Guggenheim's Sons had secured Mr. Van Cleve as

two stands of converters. At Anaconda, at the present time, six stands of converters are treating 1400 tons of matte per day.

Where did you go from Monterrey?

Back to Perth Amboy. Previous to taking charge there again, I made a trip through the West, to Montana, taking in Great Falls, Butte, and Anaconda, then through Colorado back to Perth Amboy, inspecting the various plants on the way.

Do you recall any of your impressions?

The most curious thing that impressed me on that trip

FIRST MECHANICAL FEED FOR LEAD BLAST-FURNACE, PUEBLO SMELTER, 1890.

permanent metallurgist, my position being considered only temporary. Before leaving Monterrey, I paid a visit to Paul Johnson, at Aguas Calientes, where I saw the large converters, the wonders of their day, which were engaged in converting the copper matte made from the Tepezala ore. These converters were 8 ft. across. They had been erected by Hiram W. Hixon. This was before the day of the electric traveling crane, so that the converters all had to be taken out on trucks to be emptied, and had to be taken apart in sections to be re-lined, as is still done at Mt. Lyell, Tasmania. Nowadays converters of this type are 20 ft. in diameter.

Mr. Mathewson, you must be impressed by the greater facilities now afforded to the metallurgist in the handling of his material.

Certainly. At the Mexieau plant, for instance, much less than 50 tons of matte could be treated in a day by

was not metallurgical. I had, a few months previously, bidden farewell to my old friend, August Raht, in Mexico, as he had started for Europe, intending to end his days there. I was surprised in going into the lobby of the McDermott House at Butte, to meet him and find that he was on his way to Australia. I bade him another farewell, and a few months later, I was at Pueblo and looking through the arch in the Union depot, I noticed a familiar back on the platform and went out and found my old friend again, on his return from Australia, heading for New York. Metallurgically, the thing that impressed me most was the size of the Anaconda smelter, which was considered a wonder, even in those early days. The plant, at that time, was handling over 3000 tons of ore daily, under the management of the late John S. Dougherty.

What is the present capacity of the Anaconda?

18,000 tons daily of copper ore, and 2000 tons of zinc ore.

You returned to Perth Amboy?

I returned to Perth Amboy and remained there as manager until September 1899, when the Messrs. Guggenheim asked me to take charge temporarily of a smelter at Playa Blanca, near Antofagasta, Chile, which they had leased from the Huanchaca company, the idea being that I start operations and turn the plant over to my successor in three months. Consequently I left my family at Perth Amboy and reached my destination at Antofagasta on the 13th of October 1899. I immediately put the furnaces in operation, under the charge of Ludwig Klotz, as metallurgist. But in a few months it was evident that I would have to remain longer, so the Guggenheims advised me that they would send my family down to Chile if I would remain a year. This I agreed to do, and my family all came down, with Mr. and Mrs. F. D. Allen, the present agent of the A. S. & R. Co. at Antofagasta, arriving early in 1900. I remained in charge as manager of the Playa Blanca plant until October 13, 1901, when I was recalled to New York.

Did this smelter at Playa Blanca have any interesting features?

It had many. There being no rain in that region, there were no buildings over the furnaces. In places there were sheds to keep off the sun; these were roofed with split bamboo. The furnaces presented a strange appearance. They were all exposed to the open air. The ores were refractory, and fluxes were extremely hard to obtain. The ores came from the Pulacayo mine in Bolivia, 15,000 ft. above sea-level, and were transported in narrow-gauge cars to the smelter, which was near sea-level. The water-jackets of the furnaces were supplied with salt water pumped from the sea. The water for drinking purposes used at the smelter colony was the overflow from a pipe-line, starting near Quilagua, 240 miles long, and this fluid, though clear, was anything but pure. It was contaminated with salt, nitre, borax, etc., and had to be distilled before use. In the town of Antofagasta they used sea-water largely for distilling. The ore, containing copper, lead, and silver, together with a little antimony and tin and considerable sulphur, was made into adobes by hand, mixing it with lime burned on the premises; these adobes were dried by the sun, then piled up in racks and burned with coke breeze, as ordinary mud-bricks are burned. After burning, these were conveyed directly to the blast-furnaces. The amount of impurities in the ore and the lack of fluxes made the slags extremely unsatisfactory to one accustomed to the metallurgy of Colorado, but the capitalists who were backing the enterprise did not see their way clear to advance any money to the poor miners of that country, who had no capital and could not work without some advance in cash. After using up a large quantity of slags rich in lead from Oruro, the discard from the ancient furnaces of the Spaniards, and no other lead being available, an attempt was made to use the

lead concentrates from Broken Hill, Australia, one shipment of these being tried, but there not being sufficient profit in the arrangement, we discontinued their use and substituted concentrate from Moyie, British Columbia.

Which mine?

The St. Eugene mine, in the Kootenay. This, as a business proposition, proved no better than the Broken Hill shipment, and on the advice of Willard S. Morse, representing M. Guggenheim's Sons, we gradually changed the furnaces from the use of lead to copper as a collector of precious metals. To this I objected, on the ground that the copper ores available at Chuquibambilla and vicinity all contained various chlorides, and would result in large losses of precious metals by volatilization. But Mr. Morse saw fit to insist, and the furnaces were changed as directed, with the result that the losses by volatilization proved so great that the operation became unprofitable. Meantime Mr. Morse returned to New York, the Guggenheims having merged with the American Smelting & Refining Co. Shortly afterward I was summoned to New York, and on my arrival there, in consultation with the firm, I advised that the operations of the smelter at Playa Blanca be discontinued, which was done, instructions being sent by cable. At the same time I was fired. This was a serious thing for me, as it appeared to me that all the metallurgical positions in my line as a lead metallurgist were in the hands of one company, and that company had no further use for me.

What did you do?

I took my family to Montreal, and immediately started on a still hunt for a job. I failed to secure one for six months, and was becoming desperate, when a good friend of mine, L. J. W. Jones, suggested that we enter into partnership and start a copper refinery on the Pacific Coast, possibly in British Columbia. I agreed with him that this was a business possibility, as he had a little money and could interest more capital, and I had a little of my own that I was willing to risk. I agreed to start for British Columbia and look into the situation. I had my grip packed, ready to leave, when I received a telegram from Frank Klepetko, asking me if I would come to Anaconda and look into the blast-furnace situation at the new Washoe smelter there, with a view to taking charge of the blast-furnaces if I liked the job.

That was in 1902?

Yes. In June 1902. I proceeded at once to Anaconda, met Mr. Klepetko, who took me down to the blast-furnace room, and this was in such a sad condition that I thought there was plenty of work cut out for me if I liked to take charge of it. I could see no difficulty in the position, so I accepted his offer to act as blast-furnace superintendent. I found a peculiar condition of affairs. No less than eight different men had the authority, and used it, to change the charge of the blast-furnaces as they saw fit, the result being chaos. Of the five furnaces at that time supposed to be in blast, there were never three in operation at one time. I speedily rectified this, to the amusement of the furnace foremen, who found they were

able to keep five furnaces in blast continually. Shortly after this, Mr. Klepetko accepted a position with Mr. Haggin, to go to Cerro de Pasco and build a plant there, and F. I. Cairns was placed in charge of the Washoe smelter, as manager. I was asked to take charge of the

CHUQUICAMATA IN 1899.

reverberatory furnaces and roasters. These reverberatory furnaces were at that time the largest in the world. The hearths were 50 ft. in length and 19 ft. in width, and the furnaces were smelting on an average of 75 to 100 tons per day. These compare with the modern furnace of this type as follows: 140 ft. length of hearth, 25 ft. width, average smelting 650 tons per day.

How do the costs compare?

Costs at present in reverberatory-smelting practice are about one-third of what they were then. A few months later Mr. Cairns resigned to accept a position as manager of the Michigan Smelting Co. at Houghton, Michigan, which position he still holds, and I was placed in charge of the plant, remaining there until this month.

You are leaving Anaconda, Mr. Mathewson?

Yes. I have received a flattering offer from the British America Nickel Corporation to take the position of general manager of their properties in Canada, with headquarters in Toronto. This position I have accepted, and will assume my new duties October 15.

What mines does this company operate?

The company operates the Murray mine near Sudbury, Ontario, and it is proposed to build a smelter near the mine and a refinery for the electrolytic refining of the nickel matte near Niagara Falls, on the Canadian side.

Mr. Mathewson, you have had a good deal to do with the introduction of flotation in America, on a large scale. Could you give me your opinion as to the scope of the process?

So far as my experience goes, the application of the process to sulphide copper ore is a wonderful success,

and can be utilized in nearly every case that has come under my observation. Even where a part of the ore is oxidized, the sulphide portion can be recovered by flotation and a considerable part of the oxidized ore by the original gravity methods of concentration.

What do you think of the new method of sulphidizing the oxidized ore?

From experiments tried at Anaconda, indications are that the oxidized portion of the ore forms such a thin layer on the particles of gangue, that when the sulphidizing is completed and the artificial sulphide mineral submitted to flotation, the gangue floats with the sulphide and no commercial degree of concentration is reached. In my opinion the oxidized ore, or the oxidized portion of sulphide ore is best treated by some form of sulphuric acid leaching.

What episode in your career pleased you most?

My recent appointment in Canada, which came to me wholly unsolicited.

Mr. Mathewson, you know that the technology of metallurgy is under great obligation to you and your staff at Anaconda for your hospitality, not only physically but mentally, extended to properly accredited visitors to your plant. I presume I may take it from you that you do not believe in secrecy in technology any more than our distinguished friend James Douglas.

I am of the opinion that the metallurgist with a secret process is like the ostrich that buries its head in the sand

C. H. MACNUTT, WILLARD S. MORSE, AND MRS. MORSE AT CHUQUICAMATA IN 1901.

on the approach of danger. The metallurgist who is free to give out information is certain to receive information in equal or greater proportion. It has been my experience that on account of the policy pursued at Anaconda I or any member of my staff have been welcomed at the most secretive establishments and shown everything of interest.

Furthermore, is it not a fact that anybody going to work systematically, honorably or dishonorably, as

the case may be, to get at any metallurgical method, can do so?

It is a fact. Secrets cannot be kept in a metallurgical works because so many are employed, and the cupidity of employees is always to be taken into account.

I was informed recently by a metallurgist who used to be at the old Pueblo plant that when the Guggenheim consolidation was made the three smelters that were shut down were the three secret plants, the Kansas City, the Philadelphia, and the Eilers.

There was one other secret one not shut-down, that was the Globe. It is still running, but is not so secretive as it was.

Now that you are leaving Anaconda, I am frank to say that you ought to feel proud of the large number of metallurgists to whom that smelter, under your charge, has been a veritable post-graduate school of metallurgy.

It has always been my idea to give the young technical men under me a chance, and whenever an opportunity was afforded for one of them to better his condition by going to some other plant, I have not hesitated to recommend a man suited for the particular position offered, no matter what place he occupied in our organization. I learned the value of this method in the early days of my experience in Pueblo, with the old Pueblo Smelting & Refining Co., under Mr. Geist. Many of the older metallurgists, some of whom are world-famous, were trained in that establishment, where I received my first knocks.

Who were at the Pueblo smelter?

H. H. Schlapp, of Broken Hill fame; Philip S. Morse, formerly manager of the Cockle Creek smelter in New South Wales; Tommy Ropp, as the Baron was known then; Wayne Darlington, now in Philadelphia; R. C. Canby, of flotation fame; W. W. Adams, now in California; S. D. Bridge, who made his name in Mexico; Ben Sadtler, afterward professor at Golden; O. J. Smith, of Reno, Nevada; and among the later crop, W. H. Howard of Salt Lake, E. H. Hamilton of Trail, B. C., W. J. Hamilton of Cerro de Pasco, Peru, Forest Rutherford of Douglas, Arizona.

Do you regard metallurgy as a good career for the young men of today?

I do.

Do you think that metallurgists or managers of metallurgical establishments should have a financial interest in the company with which they are connected or in other mining or metallurgical enterprises?

I do.

You are doing some interesting work in the electrolytic reduction of zinc. Would you mind saying something about it? Particularly in regard to the future of this new branch of the art.

The work done at Anaconda in the electrolytic reduction of zinc has been most interesting. The general principles involved are the roasting of the ore; the solution of the zinc in sulphuric acid; the purifying of the solu-

tion and then the electrolysis. Each step in the process must be most carefully watched, particularly the purification of the solution before electrolysis. The obtaining of a zinc sulphate solution from the ore is by no means new to the art; but the details of the process in use at this plant have many novel features—just at this time we are endeavoring to protect these by patents—and consequently I am not at liberty to divulge this information. However, I will say that this new branch of the art promises great things for low-grade copper ores and low-grade lead-zinc ores (containing zinc above 12%). By the removal of the greater part of the zinc, the ore becomes readily amenable to treatment. Many mines have large reserves of ore of this character which heretofore have been unworkable and classed as waste; and these reserves will now become available.

Would you agree in the opinion that electrolytic zinc is likely to drive retorted zinc out of the market.

No.

Did you receive the Gold Medal of the Institution of Mining and Metallurgy?

Yes, in 1911, and the receipt of this medal was the source of a great deal of pleasure to me.

Do you believe in young professional men writing technical papers?

I certainly believe in young professional men writing technical papers and contributing to the technical press, if they have anything to write about. A great many little things come up in practice that it is well to have recorded. It is a good thing for the young men to put their ideas into a crystalline shape and to get into the habit of making notes systematically. I certainly agree with you; and in this connection, I think it would be well for all our mining schools to pay a little more attention to English, so that their graduates will be able to make readable reports and write short technical articles without any great effort. The manner in which facts are presented to a board of directors by the technical men in the employ of a company has a great effect upon the actions of the said board in approving or disapproving the recommendations made.

Do you approve of the present system of settling ore-purchases on the quotations given in a technical journal? Would it be practicable to settle on the price obtained by the smelting-purchaser?

Of two evils, choose the less. I think the settlement on quotations given in a reliable technical journal is the less evil. We want to settle on the true market value of the metals. The only way we can approach that is to get the figures of actual transactions. If the technical journal or its people has no dealings in the market, if it cares for its reputation, the results are not too bad. I do not think it practicable to settle on the price obtained by the smelting-purchaser because no smelting-purchaser would be willing to give out the actual figures pertaining to his sales of metals.

To what extent is the enlargement of copper furnaces likely to go?

The furnaces in most establishments are now as large

TAPPING MATTE FROM THE BLAST-FURNACE AT ANACONDA.

CONVERTER TAPPING-FLOOR, ANACONDA, 1902.

as the ore-supply warrants. There is no limit to the length of a blast-furnace, but under existing conditions there is no advantage in the operation of furnaces over 75 ft. in length. The construction of the building to house very long furnaces is too expensive. In reverberatory-practice the limit of economical size of furnace has not yet been reached but the units are now about as large as it is safe to make them to insure regular output. When the unit in reverberatory-practice is too large, two units being down for repairs at the same time would cause serious reduction of output. On the other hand, in blast-furnace practice, any part of a furnace of the type used at Anaconda may be repaired while the rest of it continues operating normally. I believe that there will be no great enlargement of copper furnaces unless the supply of ore at some given point is enormously increased.

Referring to the saving of labor and the use of electric cranes, can you outline the extent to which such machinery has replaced manual labor?

Without electric cranes the big converter installations of the present day would be impracticable. In repair-shops and power-plants also, modern requirements demand such machinery. The builders of smelting and power machinery today always count on traveling cranes as part of the regular equipment; therefore they have no hesitation in designing parts weighing tons, whereas when only manual labor was used such heavy pieces would be out of the question. A great change has come over the laborer of today. He is accustomed to all kinds of labor-saving devices, and the man who makes his bread by the sweat—literally—of his brow around a smelting-plant is a rare specimen.

In what direction lies the further development of copper metallurgy?

In the saving of values from the flue-dust and smoke, and the similar saving from the oxidized portion of tailing. I believe the time is not far distant when the application of electricity to the copper-smelting industry will be as important as it now is in copper refining. There is room for improvement in the reduction of copper in furnace-slags.

You have had a lot of experience in the abatement of smelter fumes; do you consider that this difficulty has been overcome?

Each smelter-plant has its own particular smoke problem, and it will not be solved until there is a market for all the by-products that can be obtained from smoke. This means the utilization of the sulphur, either as elemental sulphur, as sulphur dioxide, sulphuric acid, or some other compound. In my opinion, if care be taken in the selection of a smelter site, so that the gases be discharged at a considerable height above the surrounding country, and settling apparatus, either electrical or mechanical, be installed to remove dust, no trouble should be experienced and no material damage done. The dilution of the gases with air and their discharge as high as practicable above surrounding lands is the

best way to dispose of them until the time comes when all possible by-products can find a market. The addition of water to spray the gases is inadvisable, in most cases, on account of the liability to pollute streams and water-courses with the product.

You have helped many young professional men. Would you please give some advice based upon your experience in aiding them?

The remarks above referring to the working-man apply to professional men also. I think it is well in dealing with young professional men to caution them not to be afraid to dirty their hands or clothes, but at the same time not to forget that they have spent a number of years of their lives in preparing for a professional career, and to spend many additional years at manual labor is a mistake. Wherever possible it is well to encourage young men not to neglect their social duties. When a friend or business acquaintance has a position to offer that would suit any of your young men, give them a chance at it; get acquainted with your young professional men and if there are too many of them, as in some large establishments, for personal acquaintance with all of them; see to it that your trusted subordinates attend to this matter. I think it a mistake to pay young professional men high salaries at the start, as it gives them wrong notions of their value. Give them enough on which to live decently and then increase their salaries as they merit it.

The management of men, as well as machinery, has engaged your attention. In what direction do you discern the best hope of allaying labor troubles?

The best way to avoid labor troubles is to give the laboring-man a square deal, paying the highest wages that the enterprise can afford. In these days the laborer seldom sees the capitalist who is responsible for his employment. The personal contact of the employer with the employee must be accomplished in some way, and the best way is to have the employer's representative, either the general manager or the superintendent, given full power to treat with the employees in all matters pertaining to wages and working-conditions. The general manager and the superintendent should be selected with a view to their ability to handle men. The old-fashioned swearing foreman armed with a pick-handle has gone, never to return. The modern workman reads the papers, he knows the stock market, and has a pretty shrewd idea as to just what amount of money his employers are making out of his labor and whether or no he is receiving his fair share of the profits. I believe a system of bonuses should be established wherever possible, by which the faithful employee should receive in prosperous times a fair percentage of the abnormal profits accruing to the business. Laboring-men should be encouraged to save their money, marry, and settle down in homes of their own. Amusements should be provided, but not in the form of donations. A man seldom appreciates anything acquired without an effort on his part. Anything that can be done to make a man love his work is a boon to the man and to his employer.

Manufacture of Chromates From Chromite

By Harold French

In the preparation of chromates and bichromates of sodium or potassium, high-grade chromic iron ore is essential. Ores containing less than 50% chromium sesquioxide (Cr_2O_3) however suitable for the manufacture of ferrochrome and chrome bricks, are not desired by the industrial chemist. As there is a rapidly increasing demand for chromite averaging between 50 and 55% Cr_2O_3 and low in alumina content, it will save time, money, and worry if the producers will sort the high-grade ores according to the requirements of the manufacturers of these refined salts. Although chromic iron is mined or occurs in 26 of the counties of California, and a number of these deposits contain considerable bodies of high-grade ore, there is much complaint from the purchasers that the ores are not properly sorted, so that the general average of shipments is too low for economic treatment. Alumina is a particularly objectionable constituent in chromate manufacture, although it may be highly desirable at chrome-brick plants. A better understanding of the processes described below may lead to more discrimination on the part of the producer in segregating the various grades he desires to market.

Inasmuch as the price of potassium bichromate has risen during the past two years from 5 to 40c. per lb., f.o.b. New York, domestic users of this salt have undertaken to manufacture chromium compounds for their own needs. Tanneries consume a large part of the supply of chromates and chrome alum in producing a quality of leather that will resist heat and acids. In California, the Sawyer Tanning Co. of Napa, requiring about 600 lb. of bichromate daily, decided to manufacture its own salts from Californian ores. Since the sodium salt is ten times more soluble than the potassium and much cheaper to prepare, they have established a large chemical plant at their works. While the process they are working is not a complete technical success, it serves its purpose and is a source of considerable saving. Its full efficiency depends upon a reliable supply of high-grade chromite ore.

In a large structure, roofed with corrugated iron and floored with cement, the highly soluble normal chromate of soda is now being manufactured. On the outside are sorted piles of chromic iron that have been shipped from Amador county and from the near-by Chiles and Pope valleys in Napa county. At a glance the character of three standard grades may be estimated. The best quality is fine-grained and brittle, resembling anthracite coal. This contains from 50 to 55% chromic oxide and gives the best results. A middling grade has the appearance of dull graphite, characteristic of most chromite ore mined in California, and averages 44%. A third lot,

supposed to be high-grade chromite, assays only 35% and has a rusty ochreous color; it is useless for manufacturing purposes, and the producers of it may look elsewhere for marketing their product.

After crushing dry to a fine powder, the pulp is fed into reverberatory furnaces, heated with crude oil. The charge is mixed with a slightly greater quantity of soda-ash and chalk in equal proportions. If there is much alumina in the ore a greater amount of soda-ash and chalk is added. Up to the present date, the conditions of roasting are still largely in the experimental stage. By careful pyrometric observations, the temperature is being regulated so as to control the conversion of chromite into sodium chromate of higher purity than the quality produced at first. At the time of my visit to the plant the roasting operations were conducted for periods ranging from 8 to 16 hours. After repeated rabbling the viscous mass is raked out upon a cooling-floor, where it appears as a dirty but characteristic yellow chromate of sodium.

The solution of this crude salt is effected by lixiviation in a series of tall cylindrical vats. Theoretically 100 parts of water dissolve 87.36 parts of sodium chromate. In practice a much larger amount of the solvent is used. Some difficulties are caused by the formation of sodium sulphate in the roasting-furnace, because this sulphate dissolves with the sodium chromate. It is probable that a desulphurizing roast of the ore separate from the sodium charge will prevent the formation of soluble sulphates. From the vats the normal chromate solution is pumped to the tannery, where it is boiled with sulphuric acid and converted into the bichromate. Special care is taken at this stage of the process to add no more than the exact amount of acid necessary to produce the required chemical change from Na_2CrO_4 to $\text{Na}_2\text{Cr}_2\text{O}_7$.

At this Napa tannery the rich green solution of sodium bichromate is run directly into tanks, where hides are 'paddled' by revolving blades that beat the chrome salt into the leather. This fixes the basic salt in the saturated skin, causing it to dry without wrinkling, and upon finishing the process of tanning, the leather is given the property of resisting extremes of heat and cold. Gloves made of chrome-tanned leather are most serviceable and pliable. Workmen that handle hot tools and other objects are generally supplied with gauntlets of this heat-resistant material.

Producers of chromic iron ore may well look to the industrial chemist for the sale of their high-grade ore. With such extensive deposits of chromite, soda, and lime rock available in California, a wide field for the manufacture of chromium salts appears to be available. In preparing the refined chromates for the market, it will be

necessary to go further than the stage practised thus far at the plant of the Sawyer Tanning Co. There the chromate, as soon as it is converted into the bichromate, is utilized at once in the liquid form. To produce the pure crystals the following steps must be taken: In roasting, extra care is required to prevent the formation of soluble salts other than sodium chromate. After lixiviation of the roasted pulp, the solution must be concentrated to 52° B. by evaporation and crystallized in lead-lined pans. The normal chromate crystals are then washed in centrifugals, dried and heated to about 30° in drying-drums or chambers. Under these conditions the crystals crumble into a yellow anhydrous powder that should contain over 95% of the normal chromate.

The bichromate of sodium is formed by dissolving the normal salt to a density of 40° B., and treating with sulphuric acid (chamber grade). This requires considerable exactness on the part of the operators, who will note the actual point of conversion by testing with potassium iodide and starch-paper. An excess quantity of the normal salt is added in order to bring the proportion of chromic acid up to 72.5%. The bichromate solution must be cooled in the vat until sodium sulphate, if present, crystallizes. Then the purer solution is drained off, filtered, and evaporated to dryness in an iron pot. Almost continuous stirring is necessary during the concentration of the super-saturated bichromate solution. The solidified salt should be rolled to a fine powder while hot before it is marketed. When pure it should contain 72.3% Cr_2O_3 .

The process of manufacturing potassium bichromate is similar in many respects, only potassium lye is used instead of soda-ash. It is not generally known that this industry is conducted on an extensive scale in Europe. Great Britain alone produced 10,000 tons of potassium bichromate annually before the War. Since the sodium salts can be produced at far less cost than the potassium chromates and are ten times as soluble, the demand for sodium bichromate produced from Californian chromite and soda should greatly increase during the next few years. Not only will the flourishing tanning industry of California absorb a large amount of the bichromate production, but the demand for chromium compounds as mordants and pigments should greatly increase the demand for high-grade chromite ores.

Sampling of Mines

We are indebted to Mr. Morton Welber, of New York, for the following detailed description of his sampling of the American Girl mine, in southern California. The most interesting feature of this practice is the timing of the mixing so as to mix each sample equally.

The workings were sampled throughout the supposed orebody at intervals of 10 feet. In the raises and winzes sectionalized sampling was employed wherever desirable. In view of the low tenor of the ore, it was important that sampling should be accurate. An error that may be unimportant in medium or high grade ore becomes a large

proportion of the total content when the ore is low-grade. The sampling and cutting down was performed as follows: The original cut averaged about 10 lb. per foot. This mine-sample was reduced on the surface to pass half-inch holes. The entire sample was then mixed on a mat for a minimum of 5 minutes. Great care was taken to insure each sample being mixed for at least this period. A clock was furnished for this purpose. The work was under the constant supervision of a trained engineer. His duties were confined to this department. After the sample had been mixed, as described, it was then reduced by a Jones sampler, when it was ground to pass quarter-inch holes. The sample was then mixed again on a mat for 5 minutes, when it was cut down by a Jones sampler to approximately one pound and a half. The sample was then, without further reduction, ground in its entirety

DISCARD PILE AND THE SAMPLERS.

to pass 80-mesh, when it was again mixed for 5 minutes, prior to being split in duplicate. Great importance was attached to mixing. By this process each sample in its reduction from the original, which averaged between 50 and 60 lb. in duplicate, had been mixed for at least 15 minutes.

In order to check the accuracy of the sample as cut in the mine and also in its reduction to duplicate pulps, two systems of checking were employed. A series of cuts was re-cut and given different numbers from the original tags and were treated in every respect as separate samples in subsequent reduction and assay. The series checked to 25 cents per ton. This checked the accuracy in the cutting of the sample and its subsequent reduction. The sampling work was also checked by the assay of a series of duplicate pulps. The assays were in duplicate and they checked with the original pulps, as assayed at the mine, to 20 cents. The assaying at the mine was checked by a third system whereby a group of pulps that had been assayed were put into fresh envelopes and different numbers attached. The assayer was thereby caused to check himself, which he did to 20 cents. A flux and slag assay was run every day.

Flotation Concentration at Anaconda

By Frederick Laist and A. E. Wiggi

*Early in 1914 it was decided to test, on a fairly large scale, the treatment by flotation of Anaconda slime and tailing. For this purpose a standard Minerals Separation machine was installed at the Washoe Reduction Works during May and June 1914. This was followed by the installation of a full-size Callow pneumatic machine plant. Experiments were also made, on a smaller scale, with the Froment, the Towne, the Fields, and the Anaconda flotation machines. The last-named machine was developed at this plant. In addition to the tests made in the standard Minerals Separation machine, some tests were made using an M. S. machine of the sub-aeration type.

During the series of experiments a large variety of oils was tested. Experiments were also conducted using both round-table feed and tailing to determine whether it would be better to displace the round tables by flotation for the treatment of the slime, or to supplement the round tables by flotation of the round-table tailing.

A series of tests was also made on the treatment of the mill-tailing by grinding followed by flotation to determine the relative merits of flotation and leaching for the treatment of this product. In addition, flotation tests were made on mixtures of tailing and slime.

The round-table feed referred to above is the total slime from the mill.* It contains about 35% colloidal solids and approximately 90 to 95% of the total solids will pass through 200 mesh (0.067 mm.). It assays from 2.3 to 2.6% copper.

The mill-tailing mentioned is the total discard from the mill, exclusive of the slime. It is all finer than 2 mm. and about 90 to 95% will remain on 0.25 mm. It assays about 0.60% copper.

A series of tests was first carried out to determine roughly the best conditions for flotation, using the standard M. S. machine and treating round-table feed. The following reagents were tested either alone, or in combinations: turpentine, crude petroleum, cresylic acid, stove-oil, tar oil, Caroline oil of tar, argol, sludge-acid, fuel-oil, wood-cresote, and sulphuric acid. In some of these tests sulphuric acid was used, and in others it was omitted. Also the effect of varying the temperature of the pulp upon the flotation results was determined.

It was proved conclusively that the best combination of reagents for the treatment of our mill-products was sludge-acid, wood-cresote, stove-oil, and sulphuric acid. Fortunately, of all the reagents tested, these happened to be the cheapest. It was also proved that the addition of sulphuric acid to the pulp was of decided advantage

in the treatment of the slime. In two successive tests in which sludge-acid, wood-cresote, and stove-oil were used, the slime-tailing assayed 1.25% copper when no acid was used and 0.3% when acid was used. Since these tests were made we have omitted the use of stove-oil.

The M. S. machine had 16 agitator-compartments, each two feet square, and 14 spitzkasten, and was of the standard design. This machine is known by us as M. S. No. 1. The agitators were of the standard M. S. type, the impellers being 18 in. diam. and the agitators making 265 r.p.m. This gave the impellers a peripheral speed of 1245 ft. per min. The machine required 45 to 55 hp., including motor and belt transmission loss, when operating under a full load of pulp.

SUMMARY OF RESULTS WHEN TREATING SLIME

1. The economic capacity of the M. S. No. 1 machine when treating slime, as produced from the mill at present, is approximately 80 tons per 24 hours. We have found that the tonnage treated by the experimental machine, which had agitator boxes 2 ft. square, is to that treated by the full-size machine, with boxes 3 ft. square, as the cross-sectional area.

2. The best combination of reagents for the treatment of slime seems to be sulphuric acid, kerosene acid-sludge, wood-cresote, and stove-oil. There is some question as to the real value of stove-oil—its principal function being to make a more compact froth.

3. It would not be economical to retain the round tables, as the recovery by treating the slime directly by flotation is just as high as by retaining the round tables and treating the round-table tailing by flotation. The heating of the round-table tailing-pulp, on account of its low density, would increase the cost of flotation.

4. In treating the round-table feed directly by flotation, the resulting tailing should assay 0.30% copper, or less, with a concentrate carrying not over 40% insoluble. Possibly the concentrate can be made much cleaner with no sacrifice in the recovery.

5. It is thought that the best circuit-density for the slime-pulp in flotation treatment is about 12% solid.

6. It is thought that about 70°F. will be found to be the most economical temperature at which to keep the pulp.

7. Acid seems to be absolutely essential to the successful treatment by flotation of our slime.

8. The addition of air in the last spitzkasten is of no advantage.

9. Any considerable increase in speed of the agitators above a peripheral speed of about 1300 ft. per min. seems to be disadvantageous.

*Abstract of paper presented before the Arizona meeting of the American Institute of Mining Engineers.

SUMMARY OF RESULTS WHEN TREATING MILL-TAILING AFTER GRINDING THROUGH 60-MESH

These tests were made in the M. S. No. 1 machine. Dewatered mill-tailing was crushed through 60-mesh (0.25 mm.) in either a Hardinge mill, 10 by 4 ft., or a tube-mill, 8 by 12 ft. The grinding-mills were operated in closed circuit with a Dorr classifier, the overflow of the classifier being the final product of the system and going to the flotation plant for treatment.

1. Although not definitely demonstrated, it is thought that the economical capacity of the M. S. No. 1 machine when treating sand-tailing crushed through 60-mesh is about 175 to 200 tons per 24 hours.

2. The best combination of reagents seems to be kerosene sludge-acid and sulphuric acid. However, a mixture of cresosote, turpentine, and pine-oil, in a non-acid circuit gave good results also. The non-acid circuit, however, seems to require more delicate adjustment and more careful attendance than the acid-circuit.

3. The grinding-mill makes an ideal agitator, and it is of decided advantage to add the oil ahead of the grinders.

4. The treatment of the mill-tailing ground through 60-mesh should result in a tailing assaying not over 0.10% copper and a concentrate carrying not over 30% insoluble.

5. It is thought that the best density of pulp is from 25 to 30% solid.

6. Heating of the pulp to about 70° F. seems to be of advantage, although there is a possibility that this heating may be dispensed with during the summer months without any injurious results.

7. Acid seems to be beneficial, but it is not of as much importance as in the treatment of slime.

TREATMENT OF MIXTURE OF ROUND-TABLE FEED AND MILL-TAILING AFTER GRINDING THROUGH 60-MESH

These tests were made in the M. S. No. 1 machine. It was thought that it might be of advantage to mix the slime and re-ground mill-tailing for flotation treatment.

The average portion of sand-tailing to slime in the mixture treated was 75.7:20.1 or 3.8:1. In practice the proportion of production of tailing to slime is about 3:1; thus the mixture was somewhat deficient in slime.

Although the test was not conclusive, it was decided, from observation, that it is better to treat the slime and the sand-tailing separately. Of course, the slime made in the grinding of the sand tailing is included in the sand-tailing for treatment. This slime produced in grinding the tailing is much lower grade and more silicious than the original mill slime.

TEST WITH CALLOW PNEUMATIC MACHINE

The equipment recommended by J. M. Callow for test purposes was five standard Callow cells, 2 by 8 ft., a Pachua agitator and accessory apparatus, consisting of blower and sand pumps. In addition we built a set of two mechanical agitators. These agitators consisted of a tank about 10 ft. long by 21 ft. wide and 21 ft. deep, in which revolved a horizontal shaft carrying a set of

paddles. The agitators seemed to work well and had a combined capacity of about 60 tons of slime per 24 hours.

SUMMARY OF RESULTS WHEN TREATING SLIME

1. On our slime, air agitation is not as satisfactory as mechanical.

2. The capacity of one standard Callow cell is about 15 to 20 tons of slime per day.

3. The Callow machine makes a clean concentrate, but does not give as clean a tailing as the M. S. machine.

4. The Callow machine is more sensitive and requires closer attention than the M. S. machine.

5. The cost of repairs would probably be less on the Callow machine than on the M. S. machine. This cost, however, is comparatively small for either machine.

6. The power required per ton of slime treated in the Callow system is just about the same as that required in the M. S. machine.

In all these tests the original feed was divided among the Callow rougher-cells, operating in parallel. As a rule, there was one cleaner-cell operating also. When this was operating the concentrate from the rougher-cells went to it, the cleaner making a final concentrate and a middling that was returned to the system. The rougher-cells made the final tailing.

TREATMENT OF MILL-TAILING IN CALLOW MACHINES AFTER GRINDING THROUGH 60-MESH

During the first few shifts the mechanical agitators at the Callow plant were used, but it was soon found that they were not required; that the grinding mill gave sufficient and thorough agitation.

Kerosene sludge-acid was the only oil used during this period, and was added ahead of the grinding-mill. Sulphuric acid was added ahead of the flotation-cells. The tailing for this period average 0.10% copper and the concentrate carried an average of 42.2% insoluble. The pulp was heated just ahead of the flotation-cells.

1. The capacity of the standard Callow cell when treating ground mill-tailing is about 75 tons per day.

2. No other agitation is required if the reagents can be added ahead of the grinding-mill.

3. The use of acid seems to be of considerable advantage.

4. On account of utilizing the grinding-mill as an agitator the Callow machine requires less power per ton treated than the M. S. machine.

5. The Callow machine is more sensitive and requires more attention than the M. S. machine.

The work of the Froment, Towne, and Fields flotation machines was found to be unsatisfactory; that on the Anaconda cell was of short duration, no definite results being obtained.

The conclusions drawn from the foregoing tests were that the Minerals Separation machine was best adapted for the flotation work at Anaconda. Furthermore, that the most efficient reagents would be sludge-acid kerosene, wood cresosote, and sulphuric acid.

The froth in the flotation concentrate was broken up by a circular disc revolving in a tank.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

CRUSHING in a ball-mill is the result of two actions, the impact of the falling balls and the abrasion due to their rolling.

FEW PERSONS can receive a shock of 500 volts of electricity without serious, if not fatal, effect. Instances have been recorded, however, of men surviving a shock of several thousand volts.

CRUDE PETROLEUM is used at some mines as a dressing for hoisting-ropes, and for this purpose some kinds of crude oil are excellent, but care should be taken to obtain oil as free as possible from sulphur.

POTASH from the flue-gases of blast-furnaces treating iron ores is a commercial possibility and may become an important source of supply. The Cottrell process is used to precipitate the solids from the gases.

SHEET-PIILING of wood, metal, or concrete is most useful in excavating through water-saturated ground or quicksand. When properly placed and driven, practically all the water, except that entering from below, is excluded by this method.

ASPHALT was used extensively in the construction of the palaces of Nineveh and Babylon, the tower of Babel, and the temple of Solomon. Many evidences of these remain in the petroleum-cemented walks that have endured for more than 3000 years.

CARBON MONOXIDE to the extent of 0.2% is dangerous to life if breathed for one-half hour. Larger amounts may be fatal in correspondingly shorter intervals of time. Not more than 0.05% carbon monoxide should be allowed in any mine working at any time.

THERE is no method of determining sulphuric acid in presence of sulphates except by titrating the solution with standard alkali and methyl-orange indicator. In some cases the end-point is obscured owing to precipitation of metallic hydroxides before the point of neutrality is reached.

A NOVEL METHOD for testing detonators is used in New Zealand. The detonator is crimped on a short fuse and hung so that the detonator touches the centre of a lead plate. Upon firing by the fuse, a small crater is cut in the plate, with scratches radiating from the crater as a centre. The extent of the marks is a measure of the force of the explosion.

QUALITY OF AIR in mine-workings is affected by the consumption of the contained oxygen and by the production of poisonous gases. The consumption of oxygen and

the production of carbon dioxide is accomplished by, breathing of men, burning of candles or lights, oxidation of timbers and carbonaceous rocks, and by blasting. Poisonous gases are usually produced by the blasting but may also result from the rotting of the timbers.

STAMP-MILL SHOES and dies have no standard size. Both are made of various weights, the chief difference in weight being generally due to the variable height. In shape the main difference is in the form of the shank, or neck, of the shoes, and in the corresponding socket in the bosshead. One foundry in California has no less than 40 different patterns for shoes and dies, no two of which are alike. Undoubtedly if a standard of size could be adopted it would be welcome to mill-men.

GOLD associated with calcite is by no means uncommon. In some instances the gold occurs in veins having a gangue of both calcite and quartz, in others the material is pure crystallized limestone. At the Alford mine, 25 miles north-east of Daggett, in San Bernardino county, California, coarse gold occurs in crystallized limestone, and a similar occurrence has been noted near Box Spring, 40 miles east of Victorville in the same county. At the Carbonate mine, near Oro Grande, coarse gold was found in small veins of calcite and quartz, cutting limestone and schist. These little veins were small offshoots of a large vein-like mass of limonite with lead carbonate, occurring as a replacement of limestone. Many are prejudiced against limestone as the formation for a profitable gold mine, but there is no good reason for antipathy to any formation known to carry gold, such as limestone, quartzite, or any other rock.

ALUMINUM-CHIPS from castings, used in the manufacture of automobiles, have become a valuable source of aluminum. By the old methods of treatment the recovery of the metal was about 60%, although 90% is commercially possible. Recent investigations by the United States Bureau of Mines has shown that the causes of the high loss in the usual method of melting chips is due to the difficulty of causing coalescence of the tiny globules of molten metal which are covered with a skin of oxide and dirt. Two methods can be successfully used to promote coalescence. In one method the chips are kept just above the fusion-point and the globules made to coalesce by hand-puddling, which breaks through the skin and makes the globules unite. In this method, melting is done in an iron pot heated by oil. The other method is the use of a flux that dissolves the skin of dirt and oxide, producing clean globules which can unite. The flux suggested is 85% common salt, 15% fluorspar, used in large amount (20 to 30% of the weight of chips) and mixed with the chips before charging. High temperatures are required by this method which makes the iron-pot furnace impracticable. Melting is done in graphite crucibles or in a reverberatory-furnace. Since the presence of dirt and oxide causes low recoveries, care must be taken to prevent contamination of the chips with dirt, oil, or oxidation.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

ROCHESTER, NEVADA

INTERESTING MINING AND MILLING NOTES FROM A SHAVER DISTRICT.

Through the declaration of its initial dividend of 5c. per share, payable on December 20, the Nevada Packard company has been the centre of interest in the Rochester district during the past week. Milling operations began in December, 1915. Recently a number of interesting changes were made in cyanidation practice. The grinding unit originally consisted of a 6 by 5-ft. and a 6 by 10-ft. tube-mill in closed-circuit with a Dorr classifier. The former was converted into a ball-mill after reducing the diameter to 1 ft. 4 in., with a resulting increase in tonnage from 95 to 130 tons per day. Power consumption remained practically the same. The necessary increase in settling capacity was obtained by the use of glue as a settling agent, $\frac{1}{16}$ lb. per ton of ore being added, after dissolving in warm water. Laboratory experiments proved its efficiency on this ore. The appearance of refractory sulphides in the ore led to the installation of a canvas table test-plant between the last agitator and the C. C. D. thickeners, the original intention having been to return the concentrate to the tube-mill circuit for further grinding. The concentrate proved to be higher grade than expected, and will probably be shipped to the smelter, the lowering of tailing loss more than balancing the increased cost. This is interesting in view of the fact that at both the West End and Extension mills at Tonopah, concentration was recently discarded on silver sulphide ores. On a basis of 3263 tons treated, the October costs at the Packard were

Mining	\$1.46
Milling	1.23
Development	0.62
Total direct cost	\$3.31
Office and general	0.46
Marketing	0.29
Total indirect cost	\$0.75
Total cost per ton	\$4.06

This is exclusive of interest and depreciation. J. W. Wilkey is superintendent.

At the Packard North Extension the main adit is being driven to cut the extension of the Packard orebody, under the direction of Leo Hocorton, lessee. The tunnel has been driven 800 ft. through hard rhyolite, entirely by hand work.

A promising vein containing silver-bearing calena and cerussite is being developed by J. C. Eppeleheimer, on his claims adjoining the Packard on the west. A fair sized ore dump has been accumulated.

The Rochester Mines Co.'s mill at lower Rochester is treating 120 tons of ore daily. The new additions will probably begin operations in December, increasing the daily capacity to 200 tons. The contract for the three-mile tramway, connecting mine and mill, has been let, but actual construction has not yet begun. The haulage cost per ton will be cut from 50c. to 20c., or less. The ore is now being hauled by the Nevada Short Line Railroad, a narrow gauge road built during the boom days to connect Orondo, on the Southern Pacific, to Rochester. It is now in receiver's hip.

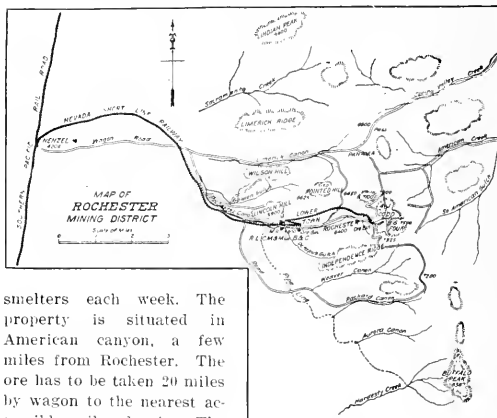

Former lessees have resumed work on the Buck and Charley

at Lower Rochester. A number of shipments of rich ore were made from this property during the early days of Rochester.

It has been persistently rumored for some time that the Tonopah Belmont-Jim Butler people were acquiring interests in the Rochester district. The election of Clyde Heller to the vice-presidency of the Merger company confirms these rumors. The cyanide-plant may now be expected to replace the printing-press as a method of ore treatment at at least one property.

Some work is being done on the Lincoln Hill mine. It was equipped with a five-stamp amalgamating mill about two years ago. This appears to have been built for decorative purposes only.

The American Mining Co. is shipping a lead-silver ore to the

smelters each week. The property is situated in American canyon, a few miles from Rochester. The ore has to be taken 20 miles by wagon to the nearest accessible railroad point. The shipping ore is accumulated by hand-sorting and jigging. It is probable that a small concentrating plant may be erected in the spring. A. L. Russell of Rochester is in charge.

Rose creek, on the Southern Pacific, 12 miles below Winnemucca, was a scene of some excitement last week, due to the discovery of some high-grade silver ore. The veins are only a few inches wide. A 40-ft. shaft constitutes the deepest workings so far.

Lee Campbell and associates, of Packard, are pushing development on their property at the head of Say canyon, a few miles west of Kennedy. The deposit is an extremely interesting one, due to the diversity of mineralization. Three grades of ore are sent to the smelter, payments being made for gold, silver, copper, and lead-content. The owners hope to be able to sort out an acceptable zinc product. The veins are extremely rich, yielding a profit after hand-hammer mining, hand-sorting, and wagon haulage of 57 miles, to Mill City. Such a variety of metals occurring in one property is, of course, a rare occurrence in this district, although it is characteristic of the Humboldt range as a whole. Within a radius of 25 miles of Rochester, gold, silver, copper, lead, zinc, antimony, tungsten, and quicksilver ores are being produced on a commercial scale.

The average number of men employed at the larger properties of the Rochester district is as follows: Rochester Mines Co., 70; Nevada Packard Mines Co., 52; Rochester Merger, 35; Nenzel Crown Point, 30; Rochester United, 7; and Limerick, 5.

SUTTER CREEK, CALIFORNIA

CENTRAL EUREKA SINKING SHAFT.—SOUTH EUREKA.—LINCOLN CONSOLIDATED TO RE-OPEN OLD MINES.—ORIGINAL AMADOR.

The Central Eureka Mining Co. began sinking its shaft below 3200 ft. two weeks ago, the idea being to increase the depth sufficiently to permit the opening of two new levels below the present bottom of the mine. Waste from the sinking is not carried above 3100 ft., being used for filling, regular mining operations are practically uninterrupted, and sufficient ore can be hauled from the main working levels to keep at least 20 stamps dropping. The company first contemplated sinking a winze on ore at 3200 ft., but this plan was abandoned. Cross-cutting a short distance to the vein will be necessary and then raising and stoping. The company reports a cost in October of \$1090 for watchmen's services as a result of the recent strike. Considerable repair work was done in the shaft and preparations made for sinking so that all of the time was not wasted while actual mining was suspended. The report shows the total expense for October to have been \$3129, of which repairs consumed \$577; pumping, \$383; enlarging and strengthening tailing dam, \$318; assaying, \$77; mill improvements, \$20; general expense, compensation insurance, etc., \$664, leaving a balance on hand of \$1236, which will be increased by the present month's gold yield and the 3c. assessment payable on or before December 1.

Forty stamps of the South Eureka company's sixty are now in operation, and the property is gradually being put into shape for greater production. The general manager, H. Maloch of San Francisco, visited the property last week.

Articles of incorporation of the Lincoln Consolidated Mining Co. were filed at Jackson last week, and considerable interest is taken in the current rumor that operations will commence in the near future on this Sutter Creek property, which the former Lincoln company sold last spring to T. Hoatson and other Michigan capitalists. The company is capitalized at \$250,000, and its holdings include the Wildman, Mahoney, Lincoln, Emerson, and several adjoining mining claims, all of which have been idle for a number of years. The Lincoln shaft has a depth of 2000 ft., and from the lowest level, 1950 ft., a long cross-cut was driven under the Mahoney 1200-ft. shaft toward the Wildman shaft a few years ago, with the intention of connecting the three properties. On the 1400-ft. level of the Wildman property, an immense body of low-grade ore was cut, which will be profitable when the mine is properly equipped. The Emerson shaft was sunk in diabase 1000 ft. east of the Wildman shaft to cut the Wildman vein at a vertical depth of 2300 ft., but had attained a depth of only 619 ft. when operations ceased for lack of money. The property stands high in local esteem, and a great future is predicted for it if properly equipped and opened on a large scale. There are two 40-stamp mills on the ground, but these and the hoisting plants are antiquated and will doubtless all be replaced by modern machinery.

During the past week progress of from 10 to 20 ft. per day has been made in unwatering and repairing the Old Eureka shaft, and the repair crew has now reached the 1000-ft. station, which is about 950 ft. from the surface, the distance between several stations not measuring the usual 100 ft. Timber in this portion of the shaft, so many years under water, appears in a remarkable state of preservation. Twenty-eight inch logs, hewn flat on two sides, were used extensively in this old shaft, and these immense timbers appear as sound as when they were first put in. A large tank and pump for lifting the water from the lower levels will be installed at the 1000-ft. station, and an 18-in. concrete floor is now being laid for this purpose. The forms are ready for pouring concrete, and some concrete has been run in for the 36-ft. piers, which will support the new head-frame. The tops of these piers are on a level with the newly-erected engine standing on the hanging-wall side of the

shaft. The hoist now in use is on the foot-wall side. The low ground around the collar of the shaft is to be filled in to the top of the concrete piers, making the ground level between the hillside and the old waste dump that borders the wagon-road. This will bring the shaft-collar on a level with the timber-shed and compressor-room, and will be a great improvement over present conditions. The head-frame, which is to be built of steel and heavy timber, will extend 92 ft. above the concrete piers. Concrete foundations for the large hoist are now being laid. Good material and workmanship is evidenced in all the company's surface construction, and strong foundations for buildings and machinery denote faith in the future of the mine. Excellent progress has been made in re-opening and equipping this old producer, considering that eight months ago there was nothing to be seen on the property save the depressions around caved shaft-collars. It now appears probable that the shaft will be cleared to the bottom early in January. After that it is understood that the company contemplates sinking a vertical shaft on the Frakes ranch, and later erecting its mill on the Goodman ranch, both of these properties having been purchased by the present company and added to the original Old Eureka holdings.

BUTTE, MONTANA

NORTH BUTTE AT DEPTH AND IN EASTERN PART OF DISTRICT.—
BUTTE GREAT FALLS, GREAT BUTTE COPPER, AND BULLWHACKER.

North Butte's Granite Mountain shaft has been sunk to a depth of over 3700 ft. Stations are being cut on the 3200, 3400, and 3600-ft. levels. Development will be hurried at these depths, to open a large quantity of ore. High temperatures that interfere with ventilation have tended to increase underground costs, and the cool weather and ventilating appliances that have been installed in the deep workings will be of great benefit. Forcing air through a canvas hose into the face has been found to be the most satisfactory way of ventilating the places that are situated a long distance from a shaft. Ore averaging 2½% copper can now be extracted at a profit, and a much lower grade of ore is being mined while the metal is high in price. Zinc ore has been developed on the 2000-ft. level, where the vein is 10 ft. wide and averages 20% metal. Several carloads were shipped to the Great Falls plant of the Anaconda company containing 17% zinc. The metal-content is expected to be higher when stoping is commenced, as there will then be a better opportunity to keep waste out of the ore. Development in the eastern part of the district, where a tunnel is being driven on the Northwestern claim, has disclosed some small sulphide veins, one of which was 18 in. wide, assaying 3.2% copper and 2.6 oz. silver. The adit is not yet in far enough to cut the large veins that are exposed on the surface, but indications are favorable and point to an extension of mining operations in this part of the district on a considerable scale.

The Butte-Great Falls company has levied an assessment of 5c. a share. This will yield \$30,000 for the treasury. A heavy flow of water was encountered on the 500-ft. level, and a new electric pump will be installed. It is also proposed to drive a drainage-tunnel that will open the 500-ft. level. Butte-Great Falls owns 186 acres north of the productive area of the district, and the veins cut at 500 ft. did not contain profitable ore. Many of the Butte veins are non-productive in the upper levels, and there is a good chance that the Butte-Great Falls veins would be productive if they were opened at a depth of 1000 ft. The company may commence operations in the Nelhart field. Several of the old silver-lead properties there are being examined.

The Great Butte Copper Co., successor to the Butte & Bacorn company, which owns claims between the Butte & Superior and Butte-Great Falls, has completed its surface plant, and un-

watered and repaired the shaft to a depth of 450 ft. It is believed that the shaft is in good condition below 500 ft., and the remainder of the water can probably be bailed out. The shaft is 1025 ft. deep, and will be sunk an additional 500 ft. Cross-cuts are to be driven on the 1000 and 1500-ft. levels to intersect veins that have been found on the surface by a network of trenches and adits.

Bullwhacker's production from its open-cut is greater than before. Underground development is also encouraging, and sub-lessees are working in different parts of the property with such success that the North Butte, which owns adjoining ground, has had many applications for leases. Much of the copper-content of the ore is in the form of silicate, and it is not probable that North Butte will mine the ore until a more economical method of treatment has been devised.

TORONTO, ONTARIO

INTERESTING NOTES ON METAL PRODUCTION DURING THE PAST NINE MONTHS.

The Bureau of Mines has collected returns from the metalliferous mines and works of Ontario showing the production for the nine months ended September 30, 1916. Following are the figures for the period, and for purposes of comparison, those for the corresponding period of 1915. It will be noted that there has been a large increase in the aggregate value, and also in the value of nearly all the individual products, due to causes mentioned in the notes appended.

Product	Quantity		Value	
	1915	1916	1915	1916
Cobalt (ore), tons	92	98	\$ 12,472	\$ 10,591
Cobalt oxide, pounds	135,337	378,732	107,363	231,947
Cobalt metallic, pounds	76,979	172,955	66,552	146,467
Cobalt and nickel oxides (unseparated), pounds	2,501	57,926	500	22,890
Copper ore, tons	1,715	21,685
Copper in matte, tons	14,057	16,989	2,024,658	6,285,930
Gold, ounces	281,712	363,955	5,826,941	7,513,734
Iron ore, tons	302,586	271,034	601,044	673,170
Molybdenite (concentrate), pounds	15,845	15,845
Nickel oxide, pounds	142,483	54,152	16,085	6,281
Nickel metallic, pounds	11,905	17,435	4,762	7,618
Nickel in matte, tons	24,054	31,046	5,369,536	15,523,000
Pig iron, tons	354,153	501,410	4,510,906	6,686,965
Silver, ounces	17,178,629	16,203,091	8,030,469	9,750,040
Total value			\$26,571,288	\$46,896,263

COBALT. The silver mines of the Cobalt district have definitely established their supremacy among sources of the world's supply of this metal. Notwithstanding the War, which has closed the European markets, shipments of cobalt oxides were much greater, both in quantity and value than in the first nine months of 1915. It will be observed that metallic cobalt is assuming an important place in the list. This is mainly due to its use in the manufacture of special alloys, principally stellite, for high-speed tools. Stellite is made of cobalt, chromium, and tungsten, and is finding a good demand from munition-makers and other workers of modern hard steels.

GOLD. The output from the mines of northern Ontario is steadily increasing, being 28% in excess of that for the nine months of 1915. Hollinger Consolidated continues to be the chief producer, accounting for 47% of the total. Dome followed with 21%, and McIntyre-Porcupine with 10%. The other important contributors at Porcupine are the Porcupine Crown, Schumacher, Vipond, and Jupiter, which together furnished 5.5%. Outside of Porcupine proper, Touch Oakes yielded \$519,149; Canadian Exploration, Croesus, and a small output from Dome Lake, amounted to over \$250,000. At Teck-Hughes (Kirkland Lake) the mine has been developed and a mill

built, which will be put in operation as soon as the power transmission-line now being erected from Cobalt is completed. Other prospects here, the Lake Shore, Wright-Hargrave, Kirkland Lake Gold Mines, La Belle-Kirkland, and Sylvanite are also being developed. This is a promising centre. In Gauthier township the Huronian mine is being worked under lease. Several discoveries of gold were made during the summer in Benoit township, but there has not been time to prove their value. At Tashota, the Tash-Orn company has bought the Wells' claim, and has erected machinery to give it a thorough test. This company is also working the King-Dodds claims. A diamond-drill has been operated on the Devanney, Reamsbottom, and Clive claims.

MOLYBDENITE. There is a demand in England for making tool-steel, and several deposits of the ore in eastern Ontario have been opened and are being worked. There are dressing plants at Renfrew and Ottawa, the latter operated by the Dominion Mines Department. Ferro-molybdenum is also being made at Orillia and Belleville. The supply of molybdenite throughout the British Empire has been reserved as a war measure, and a price of 105 shillings (\$25.20) per unit fixed for concentrate delivered at Liverpool. This approximates \$1 per pound here.

NICKEL. The Canadian Copper and the Mond Nickel companies have been working their mines and smelters at maximum capacity, and the output of nickel, contained in the matte product of the furnaces, for the nine months falls little short of that for the full year 1915. The production for 1916 will

probably exceed the production of 1915 by 20%. The valuation of the nickel in the matte has been increased from about 11c. per pound (the figure adopted by the mining companies) in 1915 to 25c. per pound in 1916.

SILVER. The mines at Cobalt continue to produce, though on a slowly diminishing scale. The quantity contained in the shipments of the nine months was 975,538 fine ounces below the record for the same period of last year; but owing to the much higher prices that have prevailed for silver the return to the mining companies was \$1,719,571 greater. Silver started the year at 56.76c. per ounce and rose to a maximum in May of 74.27c., when it receded to 63.06c. in July, reaching 68.51c. again in September. In 1915 the monthly average was 49.75c. per ounce. Nipissing still leads in production, Mining Corporation coming next, followed by Kerr Lake, Coniagas, McKinley-Barragh-Savage, Seneca-Superior, Temiskaming, etc. The flotation process is likely to assist materially in increasing the production of silver at Cobalt. It has been introduced at the Buffalo mine, where it is treating successfully low-grade ore containing 5 or 6 oz. per ton. From the gold ore treated during the period 66,347 oz. of silver was obtained, and from the copper ores 607 ounces.

A large increase in pig iron is recorded.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

ANCHORAGE. Three carloads of coal daily are being hauled from Moose creek on the Matanuska branch of the new railway for consumption at Anchorage. The population of this place is now over 4000. Large areas of land are being taken up for agricultural purposes.

ARIZONA

AGO. Over 400 Mexican miners employed by the New Cornelia Copper Co. are on strike, demanding the sliding-scale for their wages. Twenty carpenters previously downed tools, after asking for more pay.

CHLORIDE. Mines and dumps in the district are being sampled by the Western Ore Purchasing Co., F. M. Manson, general manager, to see whether a sampling-plant is warranted.

The custom mill to be erected by F. E. Steffey and others of Chicago is to be centrally situated on a hill-side.

The Tennessee mine is employing 150 men, and is shipping three carloads of ore daily to Needles. Electric power is to be available as soon as the motors are in place.

Roads into the district are to receive attention at an early date.

JEROME. In 7 days the United Verde Extension shipped 70 carloads of rich ore to smelters, a record. The 1300-ft. level is opening as well as No. 14. Plans are being prepared for a smelter. Limestone can be secured nearby.

MIAMI. The Miners' Union voted on November 27, 28, and 29 on the question of closed shop and raising the minimum of sliding wage-scale from \$3.50 to \$4 per shift. Miners are now receiving \$5.25 with copper at the present price. The Globe union decided to take no action; also that at Miami.

The Old Dominion mine is producing 1200 tons of ore daily, while three blast-furnaces and one converter are making 45 tons of copper each 24 hours. By connecting the two ends the west foot-wall drift on No. 18 level, ventilation and ore-handling is improved. The flow of water in the mine is under 5,000,000 gal. daily. Drilling and grouting of Pinal creek continues with the object of lessening the inflow of water. Flotation equipment is to be enlarged.

(Special Correspondence.)—Three modern gold reduction plants are being constructed, or will soon be under way, in the Oatman district. They will have a combined capacity of from 1300 to 1500 tons of ore daily. The United Eastern 400-ton mill is practically complete and will be operating within the next 30 days. The plant was well designed. The ore will be crushed by both ball and pebble-mills, while the counter-current decantation system of cyaniding will be used. A total mining and milling cost of \$3 per ton is estimated when the three new plants are in operation. The other two plants are being designed for the Tom Reed and Big Jim companies, the former with a daily capacity of 500 tons, and the latter 400 or 500 tons. The new Tom Reed plant will be erected just below the Aztec shaft, where a large body of ore is now being developed. This deposit is now being explored by sinking a shaft to the 800-ft. level (now down 500 ft.), and by driving on the 400-ft. level. It is 30 ft. wide, 1600 ft. long, and averages from \$15 to \$20 gold per ton. Orders have already been placed for the electrical equipment and some of the machinery, as from five to seven months' time is necessary before deliveries can be made. The general plans and specifications of the Big Jim mill are completed, but before the type of ma-

chinery is decided on, the manager, A. G. Keating, will spend a month or more studying the latest methods being used in gold and copper plants throughout the country. The Big Jim mill will be built just west of the working-shaft of the company. With these three mills reducing 1500 tons of ore daily, the output of bullion is estimated at \$30,000 per day.

Ore treatment by an entirely new process is being done at the Gold Dust plant. This process consists of a Marks rotary pulverizer and a Zimmer centrifugal separator, a combination which it is claimed will reduce treatment costs to \$1 per ton. If this end is achieved it will mean that many properties in the district having reserves of low-grade ore will be able to mill it at a good profit, which has not been possible with costs of mining and milling running from \$8 to \$10 per ton.

Oatman, November 22.

PRESCOTT. The *Courier* states that it is almost certain that Prescott will have a large custom smelter. Representatives of the Anglo-Saxon Smelting & Refining Co. are due here from England at the end of December. H. R. Croup is president, and J. E. Russell of Prescott is attorney. Options may be taken on several groups of claims. The town authorities have provided a smelter-site for the company.

ARKANSAS

In the Buffalo River district five new concentrating plants are being erected to treat the zinc ore. Ore production from the north Arkansas field in November is expected to heat that for October, the record month.

CALIFORNIA

The report of the State Mining Bureau for the week ended November 25 shows 13 new wells starting to drill, making a total of 663 since the beginning of the year. Six wells are to be deepened or re-drilled, and three abandoned. There were 16 wells ready for test or shut-off, which is usually inspected by officials of the Bureau. Since the first of the year there have been 820 such inspections that have absorbed the greater part of the time of the Bureau staff. This work has been given particular attention, for the reason that it has insured that new or repaired wells would be completed in such a manner as to prevent damage to the oil-fields by infiltrating water. However, this work is of less ultimate value than outlining proper development methods to meet various geological conditions, and steps are being taken to alter the procedure when tests are made so as to enable the Bureau to perform its more important functions. The routine work of testing has prevented widespread study and correction of damage done by improper work through the past 15 years, but a few such cases have been acted upon, and prove that repairs properly made will greatly increase the value of some properties which were badly flooded. One of the most remarkable cases of improvement is at the property of the Del Rey Oil Co. in the Kern River field, where the proper plugging of a well, by the owners working in co-operation with the Bureau, has materially decreased operating cost and also increased the productiveness of the property.

CALIENTE. About five tons of high-grade antimony ore is being shipped daily from the Big Fifty mine, 15 miles away. A mill may be erected for the lower-grade ore. The Fifty Associates Securities Co. of Los Angeles is owner.

CRESCENT MILLS. The old Crescent gold mine, one of the best

producers in the Indian Valley district of Plumas county, is being re-opened by the Philadelphia Exploration Co. The mine is to be unwatered and the mill re-built. Albert Burch is in control, with A. Buckbee as superintendent.

GRASS VALLEY. The old Syndicate holdings of 53 acres have been acquired by the Grass Valley Consolidated Gold Mines Co., owners of the Allison Ranch mine. The area of this company is now over 200 acres. The Allison Ranch will be able to mine several veins apexing in Syndicate property.

GROVELAND. The Flap Jack gold mine in Tuolumne county, fairly well equipped, has been bonded to Honolulu and New York sugar interests for \$50,000. D. Dana is making an examination.

(Special Correspondence.)—Construction of a three-mile road from the Gray Eagle copper mine to Happy Camp in Sis-

company has opened two good quartz veins on Horse creek, and is preparing to hurry developments.

Happy Camp, November 24.

HAMMONTON. On Sunday, November 26, the Yuba Consolidated launched the steel hull of No. 16 dredge. The exercises were preceded by a turkey dinner and band concert. The hull cost \$150,000, and the completed boat \$500,000. Instead of stacking tailing behind it in the river, two belts will discharge the gravel on the banks of the river.

MARYSVILLE. A temporary injunction has been allowed the Yuba Consolidated in its suit against the Marigold Dredging Co. restraining the latter from operating a dredge on land in dispute. The Court is to decide on December 8 whether the injunction be made permanent or not.

MOKELUMNE HILL. In a new shaft being sunk by lessees of

SURFACE PLANT OF CALAVERAS COPPER CO., COPPEROPOLIS, CALIFORNIA.

kiyon county proceeds. It is hoped to have it complete before winter. Arrangements have been made for installation of much equipment in the early spring. It is reported that a concentrator will be erected and that concentrate and shipping ore will be sent to the Thompson smelter of the Mason Valley Mines Co. This company recently acquired the Gray Eagle and is directing operations. William Hoerner is superintendent. Ore reserves are estimated by competent engineers to be considerable.

Numerous copper deposits in this district are claiming attention. At the Ely on Elk creek, an adit is being driven to intersect the vein exposed near the surface. The orebody averages 15 ft. in width and has been traced for 2000 ft. Recent assays gave 18% copper and \$20 in gold and silver.—Considerable work is going on at the Williams claims, lately taken under bond for \$50,000 by San Francisco people. J. E. McCoy is pushing the work at the Fairview, adjoining the Williams mine.—H. G. Boone has sold his interest in the Bon Ton group to M. A. Delano, of Grants Pass, Oregon, who is arranging for vigorous work. The W. R. West company has opened high-grade copper ore at a point 18 ft. in from the adit portal.—Several deals have been reported in the past month.

Gold mining is also active. From the Bradley mine, on Independence creek, a 12-mile road is being built to Klamath river, where it will connect with the highway. Plans have been drawn for a mill and cyanideplant, and operations are soon to begin. Rich gravel is being worked at the Atterberry Brothers' property, and an elevator will be installed in the spring. The main deposit is said to be 300 ft. wide and 8 to 24 ft. deep. Preparations are being completed for resumption of hydraulic mining at the Davis Consolidated, one of the largest placer properties in the county. The Savage-Johnson

the old Garibaldi mine, 8 miles away, rich gold ore has been opened at a depth of 50 feet.

PLYMOUTH. The Plymouth Consolidated reports as follows for October:

Ore milled, tons	7,900
Gold recovered	\$52,385
Working expenditure	24,931
Development	6,783
Surplus	20,671
Other charges, construction	6,662

COLORADO

BOULDER. The tungsten market is improving, buying being better. The Primos, Wolf Tongue, and Vasco companies are preparing to re-open leases and encourage miners to renew operations. Degge-Clark and other leaders in the independent market are receiving all the lower-grade ores offered, and much activity is observable on the part of independent miners.

A region of especial geologic as well as economic interest is that described in Bulletin 265 of the U. S. Geological Survey, entitled, 'Geology of the Boulder District, Colorado.' The area shown on the maps accompanying this report is a quadrangle measuring 16 miles from north to south by 9 miles from east to west, of which Boulder is practically the centre. The discovery of coal, oil, and gas in the region first called attention to it, and was the immediate occasion for the survey which resulted in the publication of this bulletin. The structural and other geologic features of the area, including the folds, faults, landslips, and mesas, afford attractive subjects for study and comparison.

CRESSON CREEK. In addition to its monthly distribution of \$122,000, the Cresson company will pay \$183,000 on December

10. Shares are quoted at \$9. The mine is said to be in a favorable condition. The gold output of the district in November was \$1,311,356 from 75,623 tons of ore.

GEORGETOWN. The mining situation in the Georgetown and adjoining districts is better than it has been for a long time, according to the *Courier*, and although there may seem to the casual visitor an appearance of want of 'get-up' to the town, it is more greatly due to past years of stagnation in mining, which was general throughout the United States, than to the present condition of business here. At the present time more mines are being worked and more men employed in this and neighboring centres than has been the case for years, and what is better still, more ore is being produced, ore of all grades from \$10 to \$200 per ton, and in large quantities. This being the case, why is not every mine and prospect in the vicinity being worked? The ores contain gold, silver, lead, copper, and zinc, the prices for all of which are higher than they have been, and at prices which have prevailed for a good while past, all these metals can be mined at a good profit under practical business management. The want of practical business methods as applied to mining has been the great cause of failure. The one big and most glaring reason why more mines here are not worked is the want of proper publicity, and this will never be given to the district as long as it stays in a rut. It takes capital to open any business, and although there may be good ore in the mine, still capital is needed to get it out and market it to the best advantage. Capital is what we want. How are we going to get it? This is up to the businessmen and miners of Georgetown and not to any one else. No one is interested but ourselves.

LEADVILLE. The higher price for silver is pleasing to producers in this district, as most of their ores contain a good deal of the metal, the aggregate being nearly 3,000,000 oz. yearly. The Dinero and Louisville mines yield ore assaying up to 1000 oz. per ton.

At Robinson the Progress M. & M. Co. has re-built the old Wilson mill, and is now operating it in conjunction with other mines under its control.

John Cortellini, manager of the Garbutt and other properties on Breece hill, has just returned from a short tour through the important zinc-fields of the country where the latest methods of mining and treatment are in vogue. He said that every mine has its own concentration plant. It is conservatively estimated that it is necessary to concentrate at least 75% of the total output from the mines before shipping to the smelters. Mr. Cortellini is a strong advocate of milling, and considers that if concentration has been found to be such a remarkable success in zinc mining throughout Missouri, it should be of great benefit at Leadville, where there is at present only one mill in operation. Much of the ore that is being extracted from the Garbutt and Ibox properties needs concentration, and Mr. Cortellini is still engaged in an effort to perfect suitable plans for the erection of a large mill in the district for treating this ore. The Garbutt and Ibox are now producing 450 tons daily for the smelters.

SILVERTON. Twenty companies shipped a total of 49 carloads of ore and concentrate last week. Owing to the alleged action of the D. & R. G. Railroad it is expected that there will be a coal famine in the district. Durango coal, usually \$6.25 per ton, is now from \$8.50 to \$10.

IDAHO

BURKE. The Marsh workings that are flooded are to be unwatered as soon as possible, and search made for the eastern extension of the Tiger-Poorman vein, from which the Federal company extracted \$5,000,000 net.

Development is to be resumed at the Ajax and Ambergis companies, whose claims adjoin the Hercules lead-silver mine.

The control of the Hercules mine, a large silver producer, has passed to the Day interests of the Coeur d'Alene,

through the purchase by Mrs. Eleanor Day Boyce of Portland, Oregon, of the $\frac{1}{4}$ interest in the property formerly held by the estate of the late Damian Cardoner of Barcelona, Spain. With the exception of August Paulsen of Spokane, Mrs. Boyce becomes the largest individual owner in the Hercules mine, her interest now being 7/32, while the Paulsen interest is 33/128, or a fraction over one-quarter. The aggregate interests of the Days in the Hercules now amount to 33/64, or slightly more than a half. The Days are divided into 3/32 each for Harry L., Jerome J., and Eugene R. Day, while Blanche Day Ellis, a sister, holds 1/64. The consideration named in the deed, which bears date of October 28, is \$1, but it is believed that the price actually paid is \$500,000. The $\frac{1}{4}$ interest conveyed by deed is the interest left in the estate of Cardoner, and was appraised in probate court at \$250,000. This interest was distributed to Mathilde Cardoner, widow, and the deed is made by her to Mrs. Boyce.

FLORENCE. In the Marshall Lake district, 40 miles southwest, W. Fox and two others cleaned-up \$20,000 from a 7 days' run with a Chilean mill. Ore containing \$400,000 is said to be blocked out in the Sherman property.

KELLOGG. Rapid progress in construction is reported at the Bunker Hill & Sullivan smelter. An average of 275 men is employed on the buildings, stack, etc.

KINGSTON. After an examination of the Hypotheek mine had been made by its representatives, the Rex Consolidated Mining Co. has taken a tentative option, according to rumors circulating both in Spokane and the Coeur d'Alene. The engineers' reports have not yet reached New York, however, and there is no definite assurance that the Rex directors will authorize the purchase. The Hypotheek was equipped recently with a 200-ton daily capacity concentrator and machine-drills. Regular shipments are being made to the smelter at Northport, Washington. The crushing department of the concentrator is capable of dealing with 500 to 600 tons of ore daily. The Rex company has purchased 6 claims adjoining the Rex group in the Nine-Mile district, for \$47,600 cash and 187,000 Rex shares.

MULLEN. Capacity of the Gold Hunter company's concentrator is to be increased, and the apparatus remodeled to treat the lead and silver ores. During its last financial year the output was \$614,590 from 118,764 tons of ore, yielding a profit of \$31,662.

PIKE CREEK DISTRICT. The Highland-Surprise company will practically double its milling capacity and as soon as improvements now under way are completed, thirty additional miners will be employed, according to W. W. Papesch, the president. Another cell is to be added to the flotation-plant, and the present small crushers and rolls are being replaced by 40-in. rolls and crushers of double the former size. This will give the mill a capacity of from 150 to 175 tons daily. These changes will be complete in about 10 days. Physical condition of the mine shows an immense quantity of ore blocked out for shipment. The Highland orebody is being opened for a length of 480 ft. with a vertical depth of 440 ft. Stopping is under way on this body, which shows ore at both ends of the drift from 2½ to 12 ft. in width, and carrying 14% zinc, 8% lead, and 5 oz. silver per ton. The management expects to ship not less than 50 tons of concentrate per day as soon as the improvements are completed.

Recently on the 200 and 400-ft. levels of the Northern Light mine three veins have been developed, exposing a large tonnage of lead, zinc, and copper ore, including some silver. A recent cross-cut at 400 ft. has passed through 25 ft. of ore, 5 ft. of which is solid lead-zinc ore. An average sample yielded 7.5% lead, 9.5% zinc, and 20 oz. silver per ton. B. G. Harmon is in charge.

WALLACE. The Montana Power Co. has connected up its high-tension power-lines with the Coeur d'Alene region, and has begun to serve the Douglas and other mines.

MICHIGAN

Houghton. During the latter part of November three steamers carried to lower lake ports over 3000 tons of refined copper each. The season for navigation is nearly over. More metal was moved on the Lakes this season than before.

The labor situation in the Lake Superior mining district has cleared itself in a remarkable manner, according to the *Daily Mining Gazette*. The number of men employed increases steadily now that winter is ahead, and the men are doing more work. That applies particularly to contract mining and tramming where the pay is high. Ten years ago it was proposed to eliminate contract mining—the old Cornish mining system that came to the Lake Superior district with the first copper miners. Some of the companies applied nothing but the day-wage system to all miners, but in recent years more and more of them have changed back to the contract system. When the Calumet & Hecla took over the Fay and the Bigelow mines they instituted the contract system, always popular in the C. & H. And it has resulted in greater efficiency. At the present time the men are making larger wages. Miners who are able to get better than \$200 a month are not so exceptional as formerly. This is not the average, of course, but there is hardly a contract miner in the district who is not averaging over \$5 a shift at present. Of course the contract men are the best men. And they work all the time and know their business. They are the pick of the miners. Contract tramming, at first considered a joke, is becoming more and more in vogue, and it is resulting in a much larger haulage per ton than ever considered possible. Not only that, but the men are making a great deal more money than was possible on the first scale. One gang of trammers averaged \$4.85 per shift, per man, in October.

MISSOURI

Joplin. Best grades of zinc ore advanced \$10 per ton last week, the range being \$90 to \$105. Lead and calamine were also higher. The output of the Missouri-Kansas-Oklahoma region was 8202 tons of blende, 1023 tons of calamine, and 1129 tons of lead, averaging \$95, \$54, and \$87 per ton, respectively. The total value was \$937,187, and for 47 weeks, \$30,381,854.

Owing to curtailment of work in this district, and many men going to the busier Oklahoma centres, there is a shortage of shovelers at Joplin.

MONTANA

Bannack. As the Bannack Gold Mining Co. could not get delivery on its order for a Diesel engine it will not be possible to start the new 150-ton mill. The climate is too severe to depend on water-power during the winter.

Butte. During October the Butte & Superior treated 51,450 tons of ore assaying 15.52% of zinc. The recovery was 92.5%. Zinc in concentrate totaled 15,691,000 pounds.

In the suit of Minerals Separation v. Butte & Superior, Judge G. M. Bourquin decided that the defendant is not to be restrained from paying dividends, disposing of assets, or enlarging its plant. The company was also released from the bond of \$75,000 to secure a possible judgement for infringement of the M. S. patent. The crushing plant is to be enlarged at once.

Iron Mountain. Owing to a freeze-up and shutting-down of mine and mill the Intermountain Copper company was unable to distribute its second dividend of \$8075.

Troy. If all is complete it is expected that the Snowstorm Consolidated mill will commence operations early in January. L. Greenough is general manager. Over 700 men are employed at present.

NEVADA

(Special Correspondence.)—A smelting plant of 150 tons' capacity is being erected at the copper centre of Bullion, 28

miles south of Elko, by T. M. Moe and associates. The plant is scheduled to go into operation before the end of December. Coke and crude oil will be used as fuel. The company has acquired large dumps of medium-grade ore, and in addition will take the output of leasing companies, of which nine are shipping at present.

The Hidden Treasure group of gold-silver-lead claims has been taken under bond and option by W. D. Chambers and associates of San Francisco, and work started with a few men. The property is about 1½ miles from Aura, and is owned by R. S. Carmichael and William Vore of Elko. Approximately 1200 ft. of development has been done, and a large quantity of ore exposed.

Elko, November 25.

(Special Correspondence.)—The Nevada Consolidated is working at full capacity in all departments. At the mines four or five cars of silicious carbonate ore, mostly from the stock-pile, saved in removing the overburden, is shipped daily to Garfield, Utah. This ore is said to contain 4 to 6% copper. Some comes from open-cuts. This silicious ore is used all the time in the converters at McGill, three or four cars per week. Work on the larger crushing-plant is being hurried, but on account of non-delivery of material the completion will be delayed into next year. The public appears to have finally found out, during the past three months, judging from the number of sales, and activity of the shares, to realize that it has been the cheapest stock of all the coppers. Outside of the known drilled 50,000,000 tons, the company has a large area of as promising ground as that which has been opened. Drilling operations this year have developed other extensive deposits. The metal extraction at McGill is the best of any of the large coppers. Inspiration, in Arizona, shows higher, but they deduct from the heads first the carbonate content.

At the old Giroux the Coppermines Consolidated is sinking the Morris shaft at a cost of upwards of \$250 per foot, according to those in a position to know. The mill will be completed ahead of contract time if the company is able to secure the materials.

Active work is being pushed at the Ward mine, 18 miles south of Ely, both on account of those holding the bond and lease and those having a lease on the workings.—A couple of men are at work on the Argus, across the valley from Ward. W. Stewart, on the Minerva Tungsten, south of Osceola, is employing three men. The U. S. Tungsten Co. has a few lessees extracting ore.

North in Spring valley, R. Millicek has commenced operating the mill on the Piernont property; the plant was moved from south of Cherry creek. Some Salt Lake City people are working the Grand deposit, at Muncy creek, near Aurum, and are now hauling one carload of copper ore to the smelter at McGill. The Utah people who have been doing some work on the Lucky deposit, at the old town of Aurum, have quit.

The Tungstania Mining Co. is running its mill continuously. The owners have an extensive deposit of commercial ore and with better milling facilities this should prove a winner, at one-half the present price of concentrate. Utah people are erecting a small mill at Miles spring, three miles west of Tungstania, to treat tungsten ores, which they have north and west of Tungstania.

Lacey and Clarey are working their Red Hills lead-silver mine. Their dead work, a long cross-cut tunnel and raise, is nearly finished, when they should be able to make shipments.

There is more activity than in many years and ores are being shipped from the old camp of Hamilton, 45 miles west of Ely.

Paul Moorman has just shipped another car of silver-lead ore, that assays \$100 per ton.

Ely, November 20.

Goldfield. Final figures for October show that the Goldfield Consolidated made \$17,016 net from 30,000 tons of ore treated.

Costs totaled \$4.78 per ton. Filter and flotation royalties were 4c. per ton each. Development cost \$5.65 per foot for 1896 ft. It is expected that one 500-ton flotation unit will be ready early in January.

GOODSPRINGS. To receive ore from this zinc-lead centre and

MAP OF SOUTH-EASTERN NEVADA.

other districts, Utah people are to erect a sampling-plant at Jean to handle 200 tons in 10 hours.

TONOPAH. During October the Belmont made a profit of \$90,872 from the treatment of 12,367 tons of ore. The Extension's profit was \$50,902 from 10,038 tons. This company will pay dividends of 3% and 10% on January 1.

(Special Correspondence.)—Good progress is being made in, unwatering the deep winze near the Mexican-Ophir line. The 2700-ft. level is now open and changes are being made in the 3-compartment winze. The two dividers are being removed, and a single centre-piece is being substituted, giving the winze two compartments instead of three. This is necessary to make room for the handling of the electric pump which is being lowered as the water goes down. It is expected that the 2900-ft. level will have been reached by the middle of December, when extensive prospecting work on that level will be commenced by cross-cutting both east and west at various points from the long level run by W. H. Patton many years ago. A valuable shoot of ore was discovered some time since, back on the foot-wall in the Mexican, from which over \$400,000 has already been taken. Most of the ore from the Mexican in recent years has been mined in the hanging-wall ground which has resulted in the production of several million dollars from this series of orebodies in the Mexican and Union mines.

Virginia City, November 29.

During its financial year the Union Con. Mining Co. sent to the Mexican mill 16,126 tons of ore averaging \$25.86 per ton. The profit was \$262,057. Owing to the plant being short of cyanide, ore is now being stored. The Union shaft was re-

opened from 2000 to 2500 ft. This improved ventilation and operations considerably. Exploration is under way at 2300, 2400, 2500, 2600, and 2700 ft. When the 2900-ft. level is dry a large area will be available for prospecting. Whitman Symmes is superintendent.

YERINGTON. During the third quarter of 1916 the Nevada-Douglas Consolidated Copper Co.'s revenue totaled \$146,002 from the sale of ore and precipitate. The net profit was \$60,827, after paying operating expenses, interest, bonds, etc.

NEW MEXICO

(Special Correspondence.)—The Socorro M. & M. Co.'s product for the first half of November was 18 bars of gold-bullion. —The Mogollon Mines Co.'s clean-up for the same period yielded 820 lb. of bullion and 21 tons of high-grade concentrate, from 2000 tons of ore. The new 960-ft. shaft has been timbered 700 ft., and is said to be the best work done here. Timbering will be extended to the bottom as rapidly as possible.

The Oaks Co. is making another shipment of ore to custom mill.

At the Pacific mine, the ore-bins are being filled and aerial tramway to the Socorro mill will be started this week, and regular daily shipments maintained. A test run of the tram was entirely satisfactory.

(Special Correspondence.)—The road through Mogollon is being macadamized and repaired to accommodate heavy traffic without inconvenience in winter.

D. E. Bearup, owner and operator of the Eureka mine in which a rich discovery was recently made, is scouring the place for burros to pack an accumulation of milling ore to the local custom works. The richer ore is being sacked for shipment to smelter.

Timbering of the new shaft below the 500-ft. level in the Last Chance mine is progressing rapidly, the work being conducted from two different points. The shaft is 960 ft. deep. Development will be pushed from both the 800 and 900-ft. levels as soon as timbering will permit. The Mogollon Mines Co. is operating the property.

The Socorro M. & M. Co. has installed an automatic scale at the mill terminal of the aerial wire-rope tramway from the Pacific mine for weighing all ore received from the latter property. A belt-conveyor is being erected to handle this ore between receiving bins and crusher.

The Oaks company is breaking ground in its main drainage and transportation tunnel on Mineral creek, which will eventually open the main vein systems of the district at various depths up to 1800 ft. A road to the tunnel-site has been overhauled to facilitate traffic to that point. —At the Eberle mine, drifts are being advanced both north and south from the 50-ft. level in an exploratory shaft, which is equipped with a Fairbanks-Morse 15-hp. gasoline hoist and compressor plant. —Present development on the Clifton mine consists of driving the south drift from the adit-level and raising on No. 1 orebody.

Mogollon, November 20.

TYRONE. Renewed activity is reported from the old Black Hawk silver district of Grant county. Under E. D. Lidstone the Black Hawk mine is being unwatered and re-timbered to 750 ft. Work is also under way at the Extension, Black Jack, and Rose mines.

OKLAHOMA

CARDIN. At the Bilharz company's mine the new 400-ton mill, costing \$60,000, is in operation. F. H. Gartung is manager. The machinery is driven by 150 and 50-hp. motors. Mining is done at a depth of 270 ft. The zinc and lead ores are of high quality.

By the middle of December a new 250-ton mill will be at work on the ground of the W. M. Sheridan Trustee Mining Co.,

in charge of J. W. Marshall. Prospects for a good future are considered splendid.

UTAH

ALTA. The Alta T. & T. Co.'s tunnel is considered to be near the vein, as the formation is mineralized and the flow of water is increasing.

SALT LAKE CITY. After the return of O. C. Ralston to this city from a tour of investigation in several states, the U. S. Bureau of Mines issued the following notes:

At Pueblo, Colorado, there is a zinc smelter which is the only one in the country operating on a zinc-lead basis. The zinc in complex ores of this type is first distilled, and the residue is then sent to lead blast-furnaces for extraction of the lead, silver, and gold. As far as could be learned, most of the zinc, lead, silver, and gold-contents in such ores are being recovered in this plant, but the present ore-buying conditions are such that a smelter pays for only 60% of the lead in a zinc ore, and at a figure considerably below the market value of the lead, and the same is true of silver. In fact, the present metallurgical margin between the value of the metals in such complex ores, and the price usually paid for them is so large that many people are considering entering the field of treatment of complex ores. Throughout south-west and central Colorado are numerous deposits of these complex ores, most of which are not being worked, as the total cost of smelting is at present so high as to make it almost prohibitive to treat the ores.—In New Mexico the magnetic-separation plants at Kelly, Silver City, and Hanover were visited. Each of these plants is in the complex-ore district, and is making zinc or zinc-lead products from ores contaminated with iron sulphide. The magnetic concentration plants are removing the iron from such ores. It was learned that such large losses of ore were sustained in these plants from dusting, etc., that as a rule 1 lb. of zinc is lost for every 2 lb. shipped from the mill in a concentrate. On that account methods of treatment of such ore yielding higher recoveries of the zinc should be developed and used. Plans are now on foot for doing this.—At Bisbee, Arizona, it was found that while this mining centre is reputed to be a producer of copper, it is now developing large quantities of lead and zinc ores. Lead carbonate ores, which are difficult to concentrate, are present in many of the copper mines, and are being exploited in only a few instances. As the Salt Lake City experiment station has developed three alternative methods of treatment of such ore during the study of Utah problems, it has been easy to get out an immediate solution of the difficulties in this district. The Shattuck-Arizona company has employed as metallurgist Glenn L. Allen, formerly one of the 'fellows' of the department of metallurgical research at the Salt Lake City station. It is further learned that in the Junction mine of this district a large body of complex sulphides of lead, zinc, and iron has been developed. These are very similar to the Colorado complex ores.—In the Chloride-Kingman district of Arizona considerable activity is now evident in the mining of complex ores, and throughout Arizona at various places are locations where this type of ore is being developed.—At Los Angeles, Mr. Ralston visited the plant of the Stebbins Dry Concentrator Co. In many of the Inter-mountain mining districts not enough water is available for milling purposes, and it has been found that many of the lead and zinc ores of lower grade are not being concentrated, due to this deficiency, hence a study of the various methods of dry concentration will some time be taken up by the Salt Lake station. The plant of the Western Precipitation Co. at Los Angeles was also visited, and samples of some strange products from testing by flotation were obtained. This company is exploiting the Cottrell precipitation process and in passing petroleum and other oil vapors through a Cottrell treater, some strange new products were obtained which promise to be good frothers for flotation work.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

I. D. D. DAIMPRÉ is with the Army Medical Corps in France.

E. C. MORSE has returned from Dolomi, Alaska, to Portland, Oregon.

L. J. PEPPERBERG has gone to Salt Lake City, to be absent several weeks.

F. L. SIZER has returned to Butte from a visit to the Coeur d'Alene, Idaho.

THEODORE J. HOOVER has opened an office in the Mills building, San Francisco.

J. H. BATCHELLER is manager for the Virginia Lead & Zinc Corporation, in Virginia.

EDWIN HIGGINS recently was appointed consulting engineer of the U. S. Bureau of Mines.

WILLIAM HAGUE has opened an office, as consulting engineer, in the Mills building, San Francisco.

W. ROWLAND COX has been inspecting the Socorro Mining & Milling Co.'s property at Mogollon, New Mexico.

SAMUEL COLT, superintendent of the Princeton Mining Co., at Dolomi, Alaska, has returned to Nevada City, California.

HENRY G. FERGUSON, of the U. S. Geological Survey, has just finished a complete geological survey of the Mogollon district, New Mexico.

C. C. BURGER, who was partly instrumental in the formation of the Andes Copper Co. of the Anaconda company, has sold his interest therein and has resumed professional practice at 71 Broadway, New York.

FRANCIS A. THOMPSON, head of the department of mining engineering at the State College of Washington, has recently been engaged in making an exhaustive examination of quartz properties near Pierce City, Idaho, for New York interests.

FREDERICK LAIST, formerly metallurgical manager, has been promoted to be manager of the Washoe Reduction Works at Anaconda, in place of E. P. MATHEWS, who resigned to go to Canada. C. A. LEMMON, formerly civil engineer for the Butte, Anaconda & Pacific Railway, has been appointed assistant manager under Mr. Laist, and will have charge of all operations of the Anaconda company, at Anaconda, exclusive of those conducted at the Reduction Works and foundry department. In that capacity, Mr. Lemmon will have supervision over all sociological, or welfare work, with which the company is connected.

Obituary

The death of SAMUEL JAMES is announced by the Northport Smelting & Refining Co. Mr. James was manager of the Northport company and is succeeded temporarily by R. W. Marston.

GEORGE NELSON WAGONER, well known in Nevada county, California, died recently at Boma, in the Belgian Congo, at the age of 28. He had been in the employ of an English syndicate in Africa for two years.

GEORGE W. McDANIEL, Stanford '08, died on November 21 of typhoid fever at the age of 31. He had been employed by J. E. Spurr as field engineer on mine exploration and examination work in the United States and Mexico; and by the Tonopah Mining Co. in the United States, Mexico, Alaska, and Canada. He had superintended properties in Nevada and Colorado. At the time of his death he was engineer for the Tonopah Mining Co. at Tonopah, Nevada. He is survived by a wife and son.

THE METAL MARKET

METAL PRICES

San Francisco, December 5.

Antimony, cents per pound	14
Electrolytic copper, cents per pound	35
Pig lead, cents per pound	7.25-8.50
Platinum: soft and hard metal, per ounce	105-111
Quicksilver, per flask of 75 lb.	\$80
Spelter, cents per pound	13
Tin, cents per pound	45
Zinc-dust, cents per pound	20

ORE PRICES

San Francisco, December 5.

Antimony: 50% metal, per unit	\$1.00
Chrome: 40% and over, f.o.b. cars California, per ton	15.00
Magnetite, crude, per ton	6.50-9.00
Manganese, 50% (under 35% metal not desired)	16.00
Tungsten, 60% WO ₃ , per unit	17.50-20.00

At Boulder, Colorado, there has been bidding for tungsten ore, and an advance in price is expected.

New York, November 29.

Antimony: Only a small business has been done in antimony ore. The quotation is unchanged at \$1.50 per unit.

Molybdenite: The market is unchanged at \$1.75 to \$1.85 per lb. of MoS₃ contained.

Tungsten: Europe has a good buyer, taking 100 tons and bidding for 100 tons additional. Altogether the market has been active, and most of the ore available for prompt delivery has been absorbed. The quotation is \$18 per unit, with \$20 expected before the end of the year.

EASTERN METAL MARKET

(By wire from New York.)

December 5.—Copper is strong, with the future demand steady; lead is also strong, though irregular; spelter is easier from profit-taking.

COPPER

Prices of electrolytic in New York, in cents per pound.

Tin is steady at 45 cents.

ANTIMONY

This metal is quiet, but firm, at 14.50c., duty paid, for Asiatic grades at New York.

ALUMINUM

The market is a little easier at 63 to 65c. for No. 1 virgin aluminum, 98 to 99½ pure.

Eastern Metal Market

New York, November 29.

That the copper market is quieter is admitted on all sides, but prices are practically as strong as ever. The large production, and possibility of metal being re-sold, and that shipments may be delayed is causing some apprehension, the latter for the reason that it is deliveries and not sales that actually count.

Zinc has been active and quotations are higher, although the upward trend has been halted slightly by the tendency of second-hands to take profits. Sheet zinc is now quoted at 21 cents.

Prompt lead is scarce. The leading producer is not selling at its official quotation, but is taking some January business at 7.15c., New York. Independents are well sold-up, but have made contracts at 7.25 to 7.30c., New York. Higher prices are looked for.

The week has been quiet in the tin market.

Antimony is dull but firm.

Aluminum is a trifle easier.

Excitement continues the feature in the pig-iron market, both foundry and steel-making grades advancing by leaps and bounds. Since the first of November, prices on some grades have shot-up as much as \$8 per ton. Buffalo No. 2X has sold at \$30 per ton at furnace; eastern Pennsylvania No. 2X has sold at \$29, furnace, and Southern iron at \$23, Birmingham. Basic has sold at \$30 valley (Pittsburg), and Bessemer at \$33 for standard grades, and \$35 for special. Standard low phosphorus is quoted at \$49 to \$50, delivered. The export demand is tremendous and almost entirely responsible for the situation.

The demand from both the Atlantic and Pacific coasts for ship-plates is overwhelming the mills, and sales at 5c. per lb. for the last half of next year have been made. Advances in prices are too numerous to mention *in extenso*. Wire products have gone up \$2 per ton. Steel rails are being bought for 1918 delivery at \$10 over the price paid for 1917 delivery. Re-rolling billets are quoted at \$55 per ton and forging billets at \$75 upward. The entire situation is amazing.

Revised ore prices are as follows: \$5.95 for old range and \$5.70 for Mesabi Bessemer; \$5.20 for old range and \$5.05 for Mesabi non-Bessemer. The advance amounts to \$1.50 per ton. It was expected to be but \$1.30, but this was changed by an advance in wages granted to the iron-ore miners.

COPPER

The demand for copper is easier, as should be expected after the heavy and excited buying of recent weeks. At the same time, quotations are about as strong as ever. When concessions are made they are a consequence of quiet negotiations of which the public is supposed to know nothing. Of course, there is more or less current business, and if copper were more plentiful for near-by delivery more would be doing. An Italian interest is understood to have taken a large block within the past week. Prompt, December and January metal, both Lake and electrolytic, is held at 31c. For most positions the range of quotations is unusually wide. Some sellers quote December at 34.50c., first quarter at 33.75c., second at 33c., third at 31.75c., and last quarter at 31c. On the other hand, others say that the producers are covering favored customers at 33c. for the first quarter, and that on quiet transactions 32c. probably could be done for second quarter and 31c. for third quarter. It is intimated that some of the consumers who have withheld from covering their second-quarter requirements may profit thereby. Last week allusion was made to the uneasiness with which the trade was viewing the course of prices, and conservative members continue to express similar views. They point out that, in the last analysis,

it is not sales, but deliveries, that count, and should deliveries be interfered with, re-sale metal might well be expected to appear. Last winter, when the mills in New England were embargoed, considerable copper was thrown on the market with a depressing effect on prices. Already many Eastern freight-terminals are congested, and New England has been embargoed. Again, there is the probability of speculators, and even consumers, selling metal to take the handsome profits that they can realize. A note of caution, inspired by production figures, is sounded by 'Copper Gossip,' the organ of the National Conduit & Cable Company.

The demand for brass and copper products shows no sign of letting-up, and for prompt shipments premiums are cheerfully paid. It is asserted by a mill rolling sheet copper that it cannot compete with English mills, despite the scarcity of copper abroad and the great demand for finished products. Sheet copper is quoted at 42c., mill. The London market for spot electrolytic is stronger, the quotation yesterday being £169 against £163 a week previous. Exports, November 1 to 28, totaled 19,622 tons, a rather small showing.

ZINC

Business has been good in the past few days, although on Monday and Tuesday of this week a somewhat easier tendency developed through the desire of second-hands to take profits. They offered and sold zinc at prices a little below the quotations of the producers. The latter are not so willing to sell far ahead as they were. All classes of consumers have been in the market. Prompt prime Western was to be had yesterday at 13.25c., New York, and 13c., St. Louis, although some of the producers were asking at least 1c. over these prices. For December producers wanted 13.12½c., St. Louis, for first quarter 12.87½ to 12c., and for second quarter 12 to 12.25c., St. Louis. On the other hand, dealers quoted first quarter at 12.75c., St. Louis, and 12c. for second quarter. Prominent producers believe that prices will hold fairly firm throughout the winter. The London market for spot was quoted yesterday at £59 against £56 10s. a week previous. Exports, November 1 to 28, were large, amounting to 13,334 tons. Sheet zinc for prompt shipment in carload lots is quoted at 21c., f.o.b. smelter, 8% off for cash.

LEAD

The lead situation is an interesting one for several reasons. In the first place, while the A. S. & R. Co. has not changed its official quotation of 7c., New York, and 6.92½c., St. Louis, it is nevertheless taking orders for January shipment at 7.15c. Near-by lead is difficult to procure. The independent producers are well filled with orders, and when they sell, their product easily commands 7.25 to 7.30c., New York. The leading interest is not selling prompt metal, and probably will not until its price is advanced. The trade will not be surprised to see the quotation go to 7.50c. in the next few days. There is a good demand, as yet unsatisfied. The London spot quotation is unchanged at £30 10s. Exports November 1 to 28 totaled 1363 tons.

TIN

The quotation for spot Straits tin yesterday was 45.25c., New York. In the week the price has been higher, but the market became easier as dullness became more settled. The only interest shown was in far futures. One explanation of the quiet is that the tin-plate mills only cover their contracts when the latter are signed and sealed, in a manner similar to that in which the brass mills have been buying copper and spelter. The statistics are considered fairly good, the arrivals this month amounting to 2320 tons, while there is afloat 2392 tons.

Book Reviews

FIELD GEOLOGY. By Frederick H. Lahee. P. 508. Ill., index. McGraw-Hill Book Co., Inc., New York, 1916. For sale by the MINING AND SCIENTIFIC PRESS. Price \$3.

The author presents an excellent treatise on geology which will be useful to students and engineers in the field, its size 7.5 by 5.25 in. with flexible morocco cover, making it convenient to carry in the pocket. It contains 409 half-tones and line-drawings, which so illustrate the text that even the young student can understand. In addition to the descriptive geology there is a chapter devoted to geologic surveying, in which many valuable suggestions are made to the young geologist and engineer in the field. Another chapter deals with the preparation of reports and geologic maps, and in the appendix are found tables for use in determining rocks; the solution of triangles, and a useful bibliography. In fact, it covers the field thoroughly, from the viewpoint of both the geologist and the engineer.

THE MINES HANDBOOK AND COPPER HANDBOOK. By Walter Harvey Weed. P. 1686. Ill., index. Stevens Copper Handbook Co., 29 Broadway, New York, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, \$10.

Since 1914, when Volume XI was published, there has been a growing enquiry as to when the next edition would be available. The great business in copper is responsible for this demand for a reliable reference work. It is with pleasure that we review such a compilation, which must have occupied considerable time and labor. Compared with the previous number this contains 273 additional pages. As will be observed, the title has been changed, rendered necessary by the inclusion of companies extracting antimony, gold, lead, silver, tungsten, and zinc, in fact, all metals save iron, in addition to the usual details concerning copper companies. Herein lies the much-added value to the work, and for the first time those who use such a reference are able to find data concerning active companies producing all of these metals in North America, and a few in Central and South America. We have been accustomed in the past to consult Skinner's 'Mining Manual' for many things not answered in any American work; now we will find Weed's 'Mines Handbook' helps us considerably. Owing to the War, many foreign mines were omitted, as it was impossible to procure the required information. The data concerning individual companies range from one line to ten pages. The publication contains a vast amount of new matter, added to that in the last volume. In the first 22 pages the glossary of mining terms is right up to date, including definitions of flotation and froth. The increased search for the rarer and common metals has resulted in better study of their mineral occurrences, and in the Handbook are 24 pages giving all the copper minerals and the more important of the other metals, though we miss those of tungsten and molybdenum. From page 86 to 1249, inclusive, alphabetically arranged, are all the companies previously referred to. Statistics on the metal-mining industry cover 79 pages. Herein are production figures, prices, charts, brief notes on each important metal, and trading transactions. Chapters VII and VIII show dividends, prices of stocks, and data of the world's principal mines. A list of dormant or dead mining companies covers 97 pages. Chapter X is a directory of 175 pages of presidents, secretaries, treasurers, directors, mine managers, and superintendents of the companies listed. A geographical list of all companies occupies the last chapter. In short, a valuable compendium.

ACCIDENTS AT METALLURGICAL WORKS IN THE UNITED STATES is the title of Technical Paper 164 of the Bureau of Mines just issued.

Mining Decisions

OIL LEASE—LIABILITY TO PARTNERS

Persons contributing labor, material, and cash for driving an oil-well under agreement to incorporate and issue stock in proportion to their contributions if the well comes in, otherwise each to lose what he put in, are partners and are jointly liable for labor debts incurred by one of the partners in drilling.

Roberts v. McKinney (Texas), 187 Southwestern, 976. July 3, 1916.

COAL LANDS—NOTICE OF FRAUDULENT ENTRY

A coal company acquired a bond for a deed to a large quantity of land, 800 acres of which was then a part of the Public Domain and was known coal land. Subsequently the obligor obtained patents through dummy locators and conveyed the land to the company. Held, that the company was chargeable with knowledge of such facts that it was not entitled to protection as a bona-fide purchaser. The stockholders of a corporation which has purchased coal lands previously patented are not disqualified by such act from making individual entries of their own, as the acquisition by purchase after patent of coal lands is not counted as a "single entry" allowed by the statute.

Northern Colorado Coal Co. v. United States (Colorado), 234 Federal, 34. May 1, 1916.

OIL AND GAS LEASE—COVENANT BREACHED—DAMAGES

An oil and gas lessee who has assigned a portion of his interest in his leases and agreed with his assignee to pay all delay rentals until oil or gas is produced and who, although stipulating that he is not to be bound to make explanations, agrees that before he will suffer any leases to lapse, he will notify such assignee, and will assign to him all leases which he may not desire to keep alive, thereby impliedly covenants not to dispose of such leases to a stranger without the consent of such assignee. Such a covenant being personal would not pass with the lease on assignment to the new assignee. In estimating damages for breach of such covenant and subsequent lapse of the leases, it is proper to take into account the selling-value of the leases at the time the right of action accrued.

Millan v. Bartlett (West Virginia), 89 Southeastern, 711. September 12, 1916.

RAILROAD PATENT—COLLATERAL ATTACK BY MINERAL CLAIMANT

The plaintiff originally located mineral lands and mined ore thereon. Long prior to his location the land in question had been placed by Congress within the limits of a grant to the Central Pacific Railroad Co., and patent thereto was issued under the terms of said grant to defendant's predecessors in interest while the plaintiff was still in possession of and mining on said ground. Later the plaintiff abandoned his claim, and years afterward came back and re-located the land as a mining claim, on the theory that it had been excluded from the railroad patent as mineral-bearing land. Plaintiff's claim of title was based on this later location. Held, title vested in defendant under the railroad patent. The attempted exception from said patent by the Land Department of "all mineral land, should any such be found in the tracts aforesaid" was void on its face. The issuance by the Department of a railroad patent was in itself an adjudication that the land was non-mineral, conclusive against all collateral attacks. A subsequent locator is not in privity with the Government in the sense that would permit of a direct attack by him on the validity of the patent.

Vore v. Ephram (California), 159 Pacific, 719. August 2, 1916.

Industrial Notes

Information supplied by the manufacturers.

Pumping Water With Compressed Air

One of the most interesting air-lift plants in the South-west is the one on the J. A. White ranch, three miles north-west of Fort Bliss, near El Paso, Texas. One class N-SO Chicago pneumatic compressor pumps two wells, each 600 ft. deep, the water standing 250 ft. from the surface. The compressor forces the air down into the wells, and although they are not yet entirely free from sand, the water is raised in sufficient volume to supply a town of 2000 inhabitants.

PLANT FOR PUMPING WATER BY COMPRESSED AIR.

Class N-SO compressors are made in four standard strokes, 8, 10, 12, and 14 in., with capacities from 70 to 300 cu. ft. They may be supplied portable (on truck) or skid mounted as well as stationary, and are manufactured by the Chicago Pneumatic Tool Company.

New Type of Mechanical Oil-Pump

The oil-pump shown was designed for the lubrication of stationary and portable steam or Diesel oil-engines and air-compressor cylinders. The manufacturers, the Lunkensheimer Co. of Cincinnati, Ohio, exercised great care in the selection of the materials used in the construction of the pump. As practically all operating parts are within the body and either immersed in oil or automatically lubricated, the greatest durability possible is attained.

The operation is as follows, reference being had to the accompanying illustration: Engine-link B-50377 is attached to eccentric rod or other moving part of engine and connected to link B-50376 by a rod of proper length. Line check B-7354, threaded for 1-in. pipe, is furnished for every oil outlet on pump and is attached as close to the steam pipe as possible. The position of the link B-50376 on rod RB-1754A, governs the arc of travel of ratchet-wheel I-1995. Gear I-3965, revolving with ratchet-wheel I-1995, imparts motion to pump-plungers through the mediums of gear I-3965 on eccentric shaft and eccentrics S-625A. Auxiliary plungers being suitably connected with force-pump plungers, move in unison therewith. On the up-stroke of auxiliary plungers, oil is drawn through strainers in bottom of holders SB-402, into auxiliary cylinders B-51841, from where it is forced on downward stroke through tubes CT-24, and passage in parts B-51829 to sight feeds G-52M. As the oil drops through the sight feeds, it is drawn into force-pump cylinder on the downward stroke of the plungers S-1939, from where it is forced upon the upward stroke through unions B-6126 to the cylinders to be lubricated. The quantity

of oil desired fed is regulated outside the body by auxiliary pump-plunger extension stems RB-2129. Regardless of the level of oil in reservoir, the lubrication of such parts within the body constantly requiring same, is automatically taken care of by an arrangement provided at the bottom of the force-pump plunger.

The pump operates only while the engine is running, and automatically feeds more or less oil according to the speed of the engine; consequently there is no waste of oil. Every outlet is provided with a sight-feed. These are large, will not

NEW TYPE OF OIL-PUMP.

become oil splashed, and the dropping oil can be plainly seen from a distance. Independent feed regulation for each outlet is also provided. They can readily be adjusted without the use of tools or the removal of any of the parts. The filling hole is large for convenience in filling. A sliding cap, to prevent dirt from entering, is provided, and within the opening is a bronze strainer which can readily be removed for cleaning. The pump can be had with from one to four feeds, the one-feed having a capacity of one quart or half-gallon, the two-feed, half-gallon or one gallon, and the three and four-feed, one gallon.

The trade name 'Invincible' has been given to the apparatus.

A 2000 ton mill is being erected at the Ray Hercules copper mine in Arizona, for which the DEISTER CONCENTRATOR Co. has been awarded a contract to supply 3 units of Overstrom tables of the latest type. This order consists of 4 roughers and 1 cleaner for each unit, or 15 in all.

Bulletin 201 of the ROLLER-SMITH Co. of New York briefly describes its portable storage-battery equipment for use with the firm's hand-tester on rails.

Bulletin 31 of the MINE & SMELTER SUPPLY Co. of Denver deals with the Lindsay oil-furnaces and burners, as used in assay-offices.

EDITORIAL

T. A. RICKARD, Editor

SPEAKING of patents, it is interesting to note that the Chilean law allows rights to anyone bringing forward a new application of another's patented invention.

SILVER continues strong at the pleasant price of about 75 cents per ounce. Prospects are good for the maintenance of a market favorable to the miner. Chinese exports are calling for silver in exchange and the European governments continue to buy silver for minting into subsidiary coin.

CURVES of the cost of living and of gold importation are found on opposite pages of *The Analyst*, suggesting the possible relation of cause and effect. The depreciation of gold, following upon our accumulation of a plethoric stock of it, is one reason why the cost of domestic supplies has risen so uncomfortably.

TENNESSEE COPPER has passed again into the hands of the Lewisohns, who first made it a success. A re-organization of the company has followed the resignation of Mr. Utley Wedge, who is followed, as president, by Mr. Adolph Lewisohn. We note, with pleasure, that Mr. J. Parke Channing also joins the board of directors.

REFERRING to the flotation decision, discussed on another page, it is necessary to note that the life of the basic patent, No. 835,120, is short. It will run as long as the British patent No. 7803, of which it is a duplicate. The latter dates from April 12, 1905, and has a life of 14 years, that is, to April 12, 1919, or a little over two years more. This is an important point that will become prominent in the discussion of the subject.

SECRETARY LANE'S annual report includes an account of the work done by the U. S. Bureau of Mines under the direction of Mr. Van H. Manning. The record includes sundry remarkable items, such as the extraction of \$1,000,000 worth of radium from carnotite ore mined in Colorado. During the year $8\frac{1}{2}$ grams of radium was produced at a cost of \$40,000 per gram, as compared with a market price of \$100,000. Most of this was delivered to the two principal cancer hospitals. Another important item is the claim that in the Rittman process the Bureau has perfected a cracking method for producing gasoline from crude oil at a cost of 6 cents per gallon. Controversy is rampant over this claim, but we hope that it may be fully confirmed in due course. The saving of \$20,000,000 worth of natural gas in the Blackwell district of Oklahoma and the development of an electrical furnace that will save \$10,000,000 in the brass industry

are two more feats recorded to the credit of the Bureau. Some of the newspaper summaries sent out from Washington savor of sensational advertising, and we regret that such methods should be deemed necessary to win public support for the Bureau. It is doing good work and needs no exaggerated stories to commend its labors to the special public interested in mining.

ON another page we publish a short but vivid account of the launching of another dredge on the property of the Yuba Consolidated Goldfields Company. This is written by Mr. Walter S. Weeks, of the University of California, and is delightfully illustrated with the photographs he himself took. Last week we quoted some of the figures of yield and cost at this celebrated gold-dredging mine, showing that the yield was 12.87 and the cost 3.7 cents during the first half of the current year. We are informed by Mr. W. P. Hammon that the type of boat described in the article will dig for $3\frac{1}{2}$ cents per cubic yard in the Yuba alluvium, where the depth of gravel below the water-line is 80 feet and the height of bank above water is 20 feet, so that the total depth of digging is 100 feet. A dredge of this kind will move boulders weighing four tons, but at Marysville the absence of any such masses of rock is a favorable feature, the largest weighing barely one ton. The power of the machine is shown, however, by its ability to knock off projecting points of rock, such as the basalt dikes protruding through the false bottom of tuff. Roots of trees and logs embedded in the gravel are the chief nuisance to the dredge-master, but even of these there is not much to interfere with regular excavation. The new dredge is almost a duplicate of its predecessor, the chief difference being the double stacker required to keep an open channel. Such improvements as have been made in the construction of this machine are mostly in the minor details that contribute to greater strength and to operation at a minimum cost, which means the overcoming of the liability to breakage and the consequent nearest approach to continuous running. The Yuba Consolidated is the biggest and best dredging enterprise in existence. There remains enough ground to operate for 12 years at the rate of 150,000,000 cubic yards per annum. The company is controlled in Boston.

IN this issue we publish another letter from our Mexican correspondent describing the real conditions prevailing in the interior of that ungoverned country. His description of the shifts to which Carranza has been put in order to raise money should prove illuminating. Re-

pudiation of one set of notes, bearing the seal of national honor, has been followed by the creation of new notes that within six months have fallen to the vanishing point. This destruction of paper-values has made it difficult for the *de facto*, more accurately the *pseudo*, government to satisfy the soldiers in its employ, so that discipline passes easily into desertion, setting loose a swarm of marauders. Cabrera's law regulating debts is worthy of *opera bouffe*. As is usual during a revolution, the debtor discards his obligations, so that the new decree is only an impudent legalization of accomplished depredation. The recent attempt to enforce payment in gold was a fiasco, of course, because there is not enough to go round, even if public confidence in the Government were such as to warrant the use of the hoarded coin in a world of flimsy paper. The banking position is as bad as it can be. Cabrera's baiting of the banks has only failed because the vaults are physically irresistible to anything except dynamite. From what our correspondent states, it appears likely that even explosive methods of finance will be adopted in the last resort. The Burton Wilson incident is significant as showing the difficulty of obtaining information without subjecting the informant to Mexican reprisals. If Cabrera and Carranza broke faith with the American members of the Commission, as is stated, it is high time to cease polite conversations with them. We believe the story told by our correspondent, who has proved singularly accurate in his previous letters. Famine and typhus are spreading over the devastated country. Zapata and his band are on the rampage still, Felix Diaz is somewhere on the edge of things concocting a new revolution, Villa is capturing cities and looting them as heretofore, Carranza is fulminating decrees and enacting paper laws, Washington is making phrases to pass the time of watchful waiting, and Mexico is sinking ever deeper into the abyss of perdition.

The Human Side of the Engineer's Work

We have received a short account of the Congress of Human Engineering that was held at the Ohio State University in the last week of October. This conference was designed to discuss the human factor in industry from various points of view, notably from the standpoint of the employer, superintendent, engineer, laborer, employment agent, welfare worker, economist, and teacher. All the students in the College of Engineering and in the Department of Economics and Sociology were required to attend, so that a considerable body of young men in the University of Ohio had the chance to learn something that should prove of great use to them. The various addresses delivered during the three days of session were intended to emphasize the fact that the engineer, in order to attain the highest usefulness to himself, to his employer, to the workmen, and to society as a whole, must be trained in a knowledge of the psychology, needs, possibilities, and weaknesses of the workers—in short, he

must do his share in bringing peace into industry, and to do that he must be equipped with a sympathetic knowledge of human nature. This conference appears to have achieved its purpose in bringing this point of view into large relief. The progress being made in social betterment throughout the country received proper recognition. Among the notable expressions of opinion we quote the following. Mr. W. A. Knight said: "Engineers are fast awakening to the fact that there can be no real efficiency in production without willing co-operation on the part of workmen." Mr. C. C. Morris: "The engineer of the future will be one with a more thorough training in the fundamentals, with a knowledge of men and things, and a sympathy broad enough to see even in the most illiterate immigrant not only a human being but a future American citizen." Mr. C. R. Dooley said that the meetings gave a "lasting impression that engineering is not altogether mathematics, and that human interest is not altogether sentimental." Mr. Charles R. Hook remarked: "Very little can be accomplished by any one individual in any industrial establishment entirely through his own efforts; it is his ability to obtain the co-operation of all those who work with him . . . that really counts." Mr. S. P. Brush acknowledged that "engineering courses are narrow to the extent that they deal only with things" and that "today the human element in all industry is of paramount importance." Finally, we quote Mr. F. H. Newell, who laid stress on the fact that "the full efficiency of any man, whether employer or employee, is the outcome of goodwill, of the proper mental attitude, such as is attained only when men have a close personal sympathy and a feeling that each is receiving the best which the conditions afford." He also said that "industrial or engineering success for any one man or class of men does not involve the corresponding distress of other men; but rather the contrary," and that "no working-man desires to be considered as an object of charity, but each has a proper right to demand equity." These sentiments do credit to the hearts as well as to the heads of the gentlemen quoted. They represent a composite opinion that it is a pleasure to record. Manifestly it is illogical to lay emphasis on the growth of the democratic ideal and then permit employers of labor to treat men that have become American citizens as if they were peons in the Mexico of today or serfs in the Russia of yesterday. It is equally foolish for engineers to talk about efficiency and then to spoil the usefulness of the chief implement of engineering—the worker—by handling him as if he were a bit of cotton-waste. And is it not also a blunder to prate about 'safety first' and then to treat so dangerous an explosive as collective bargaining as if it were a cylinder of sawdust? Is an engineer truly educated that regards labor organization as a nuisance to be tolerated or suppressed? These are some of the thoughts evoked by reading about this Congress of Human Engineering—we do not like the name of it, but it will serve. We do like the idea behind it, the intellectual sympathy that gave it momentum and that produced so fine an expression of opinion, for we

number ourselves with those that regard the labor problem as the most serious to be faced in this great industrial democracy. It is becoming more serious every year as the immigrant becomes Americanized into the rights and privileges of a citizen in a republic. The rise in wages caused by the War boom and the shortage of labor due to the check upon immigration are sure to be succeeded, when peace is declared in Europe, by a resumption of immigration and a drop in wages, inevitably inciting protests and strikes that will have to be met fairly and courageously. Mining will suffer from them, for a time, and engineers will have to play a part in adjusting them. They can do so, to the permanent advantage equally of those by whom they are employed and of those whom they employ, if they acquire a sympathetic knowledge of the conditions of labor, its rights and its responsibilities. The editor of an independent paper can sympathize with them—the engineers—because it is impossible to be just without antagonizing both parties in the eternal quarrel—a stupid quarrel—between capital and labor. We, for example, have never discussed a strike in a mining district without being anathematized by the labor-union and at the same time condemned by the company management. That, of course, is a compliment to our effort to be fair. So also the engineer, in his anxiety to be humane, may be reprimanded by the head-office, and in his desire to defend the rights of his employer he may be damned—or dynamited—by the men formerly under his direction. However, we see a great improvement. The more sagacious among presidents and managing directors realize the necessity for reasonableness—indeed many of them are leaders of enlightenment in this phase of human philosophy. The divine right of Baer and the anthracite trust is as much an exploded fallacy as the holiness of kingship. Nevertheless the engineer still occupies a middle position of much difficulty; it is a strong character that can escape on the one hand being made the tool of a soulless corporation and on the other hand becoming victim to an irresponsible conspiracy of walking delegates. It is in such a dilemma that the engineer proves himself educated in more than mathematics, versed in more than maxims, neither a pedant nor a brute, but a man and a citizen.

American Capital in British Columbia

In the course of a recent journey of observation through British Columbia, the present writer's attention was called to the fact that most of the important mining enterprises in the Province are controlled by American capital. It is true the Consolidated Mining & Smelting Company of Canada is a conspicuous exception, **but** the exception only serves to emphasize the general trend of affairs in that important mineral region. During the time of our visit the subject was brought to public notice in a speech by Mr. Lorne Campbell, the Minister of Mines, who had been attacked by the local

press of the opposite political party for his goodwill toward American operators. He replied that he was not concerned as to who developed the mines of the Province so long as they were developed. He recognized that the War had put a stop to the supply of money from England and suggested that capital for the purpose was not available just now in Canada. In the Sandon district, for example, out of 22 companies operating mines no less than 17 are backed by American capital, so said Mr. Campbell. He pointed to the fact that the principal mines of Rossland had been opened up by Americans, chiefly from Spokane and the Coeur d'Alene, and he spoke approvingly of the splendid work done by the Granby and Britannia companies, concerning which our readers can form their own opinion if they read the descriptive articles appearing in our pages. The Minister of Mines went further and expressed the hope that not only would American money become increasingly available for the development of the mines, but that capital from this side would be furnished for the erection of refineries in British Columbia, so that the base metals would not be exported to distant points in New York or Oklahoma. The blister copper made at Anyox, 550 miles northward from Vancouver, is sent to the Nichols refinery in the State of New York, 3300 miles eastward from Vancouver. During the past summer, matte made at Anyox has been shipped through Seattle across the border to Grand Forks to be converted, and the resulting blister copper then transported to New York. The copper concentrate from the Britannia mine is shipped to Tacoma. Zinc concentrate from the Kootenay region goes to Kansas City to be roasted for the manufacture of sulphuric acid, the residue after that operation being forwarded to Oklahoma, where it yields its zinc, and then to Norfolk, West Virginia, where finally the gold, silver, and copper are extracted. It is not surprising that the suggestion of establishing a refinery on the coast of British Columbia wins support, nor that American capital is invited to take the project in hand. From our own enquiries among representative Canadians, we ascertained that the Minister of Mines did not voice the opinion of any political party in this matter, but that the people of the Province generally are thoroughly in accord with the views enunciated by him.

Why should it be otherwise? Not only have Americans furnished the capital, but they have supplied technical talent of the highest order, so that mines heretofore unproductive have developed into centres of living industry. Many of the Americans employed at the mines and smelters have become naturalized, and all of them have proved good citizens in the country of their adoption—not of exile—at a time when the patriotic spirit of Canada has been thoroughly awakened by the great events in Europe. In short, the American in British Columbia is a welcome friend, not a foreigner. This is the consequence of their spirit of co-operation. They do not use their influence, as employers of labor, to corrupt the legislature or the municipality in order to gain special privileges; they simply behave as good citizens and

wide-awake developers of the mineral resources of the Province. That is a relation complimentary to the Dominion. In countries weakly governed it is difficult to do anything without being 'held up,' which, in the sequel, means compliance with methods of corruption. Canada is no so-called Latin-American republic ready to be the prey of an unscrupulous exploiter. The Government, both Federal and Provincial, may not be immaculate, but it offers no special temptation to alien corruption. In short, what is called the political 'penetration' of foreign capital and the commercial 'infiltration' of foreign interests in an insidiously disintegrating way is not possible in a country so well governed and so strong in its spirit of nationality as is Canada today. It is no Nicaragua, no Mexico, nor even Italy. Mr. Robert Herriek in his recent book, 'The World Decision,' tells how German capitalists got hold of hotels, the factories, the shops in Italy, and at the same time suborned the politicians, from Gioletti down. He also dwells upon the fact that much of Mexico's misery is traceable to the pernicious influence of foreign capital upon its domestic policies. On the other hand, the United States 'has drawn upon the European board as upon an international bank, but we have absolutely controlled the disposition of the moneys borrowed.' The beneficial exploitation of our own country by foreign capital has entailed no surrender of industrial or political power. The position of Canada is exactly the same. The peoples north and south of the unfortified international boundary go into the house of their friends with no thought of interfering with the domestic arrangements.

On the contrary, we see many reasons why the co-operation of capital and technical knowledge from the United States should be brought to bear on British Columbian mining enterprise. Our contiguity is convenient and attractive. This country is going to be a lender of money, instead of a borrower; the accumulation of capital in consequence of these years of abnormal prosperity is destined to create a surplus that will have to be used fruitfully. Why go to China and Peru, to Chile or Siberia, when a resourceful healthful mineral region is across the street, as it were? Why deal with people whose language we do not speak and whose ways of living we cannot understand if others between whom and us no such barriers exist are much nearer? A welcome is given by the people of British Columbia. They recognize that British, and even Eastern Canadian, capital is not going to be available in large amount, and being Western, progressive, and energetic, they turn naturally to the capable operators and engineers in our West for friendly assistance. We commend the matter to the consideration of our readers, believing that it will prove of mutual benefit to the two parties chiefly concerned. Those desiring information concerning the mining regulations, the distribution of the mineral deposits, the facilities of transport, and the like, should address themselves to the Provincial Mineralogist, Mr. William Fleet Robertson, at Victoria, to whose courtesy we can commend them confidently.

Minerals Separation Wins

On December 11 the Supreme Court of the United States, by unanimous decision, reversed the finding of the Court of Appeals in San Francisco in the case of Minerals Separation v. J. M. Hyde. The decision substantially affirms the opinion of Judge Bourquin in the District Court of Montana and upholds the validity of the basic patent, No. 835,120, owned by the Minerals Separation company, a British corporation. Thus the first phase of the flotation litigation in this country is concluded and the owners of the froth patent are now entitled to collect royalty from all those whom the law has defined as infringers, that is, anybody making a mineral-laden bubble for metallurgical purposes. What tax the Minerals Separation will, or can, impose we do not know. That will be disclosed in due course. Some facetious lawyers have suggested that the measure of benefit is the difference in the cost of the oil saved by the use of the M. S. patent as compared with the amounts used in the prior art. Ordinarily we would assume that the 'customary' royalty to be allowed by the Court would be that already specified in existing contracts, such as the one with the Anaconda and Inspiration companies, as published in our issue of September 16, but it is not improbable that Minerals Separation will endeavor to make the infringers pay more than its present licensees, who showed a willingness to recognize its patent rights before the Court compelled them to do so. In the Anaconda-Inspiration contract the royalty ranges from 12 cents per ton on a daily output of 4000 tons to 4 cents per ton on a daily tonnage of 30,000. On lead-zinc ores the royalty has varied with the richness of the ore, and has ranged between 15 and 20 cents per ton. On gold ores the usual royalty has been 25 cents per ounce of gold. These figures furnish a basis for guessing what may be demanded. We do not hesitate to say that the Minerals Separation people will make a serious blunder if they try to exact punitive royalties. The litigation is not necessarily at an end; the Elmore air patent has not been cited as yet against the froth patent and it offers scope for much more trouble, particularly as the American rights to this prior patent are now owned in the United States. Minerals Separation has a chance to avoid further bitterness of feeling by being reasonable—even generous. A royalty of 10 cents per ton on copper ores and of 25 cents per ounce on gold ores would do no great hurt to anybody and would give the patentee an income of at least \$3,000,000 now, with the prospect of a great deal more in the future. We note that the British company has transferred its American rights to a new corporation registered in Maryland and called the Minerals Separation North American Corporation. This is done, we presume, to remove the stigma of the foreigner; but we submit that prejudice against the company can be obviated much more effectively by a display of generosity toward users of the process instead of taking reprisals such as would invite litigation that might out-last the short life of the patent.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

A Matter of Principle

The Editor:

Sir—The 'reply' of the editor of the MINING AND SCIENTIFIC PRESS to the writer's communication of November 6 bears out the impression that some of its Eastern readers conceived in the first place, namely, that the securing of action by the San Francisco section of the American Institute of Mining Engineers on the so-called Shockley episode, and the publication of the objectionable matter in the MINING AND SCIENTIFIC PRESS, were more for the purpose of making copy for that journal, than to do justice in a controversy involving "a matter of principle," and in which the editor would make it appear "a wrong is done to a member of our profession."

The editor takes the opportunity in his 'reply' to impugn the writer's integrity and thereby offers a gratuitous insult. No notice would be taken of this, however, and, so far as the writer is concerned, the incident would be closed, if the editor had not followed it with a misleading statement in which he, with evident intent to deceive his readers, apparently quotes from the writer, but quotes wrongly, omits important portions of the statement, and thereby does the author of them gross injustice. Furthermore, in order to indulge his well-known propensity for making a quip, the editor "takes a fling" at the anthracite industry which lacks only one essential—the truth—to give it justification.

The misquoted statement which the editor attributes to the writer is made in the following tenor: "Mr. Parker's estimate of the earnings of the anthracite miner is \$628." Mr. Parker made no such statement. What he did say in a letter to the chairman of the Anthracite Section, and which was sent to Mr. Shockley was that in a report to the Anthracite Coal Strike Commission "a statement by the Lehigh Coal & Navigation Company showed that the *contract miners* in their employ in 1901 earned \$738.84, which, with the increases in 1902 and 1912 would make the wages of their contract miners at the present time for the same number of working days, \$894," and that on the same basis of deduction the average yearly earnings of *all underground employees of the same company* would be \$628. The latter figure included the wages of door-boys, drivers, and all other low-priced labor. The editor has compared the highest priced labor in the Colorado mines with the average of all underground labor in the employ of one anthracite company. It is to be noted that in the foregoing extract

from the letter to the chairman of the Anthracite Section the writer said "for the same number of working days" as in 1901 the earnings of the anthracite miners for this one company in 1915 would be \$894. The statistics for 1915 were naturally not available on October 13 of that year, however the editor of the PRESS may desire to distort the statement. They have since been published and show that the anthracite mines worked an average of 230 days. In 1901 they worked 196 days, the ability to earn in 1915 being, therefore, increased by 17% over the above estimate for that year. The editor may draw his own conclusions as to the correctness and fairness of the manner in which he has "quoted" the writer.

The writer's present position is one of confidence and trust; for twenty-five years he held a similar position with the United States government, and so far as he knows was never guilty of a breach of faith. It is a little late in life to break a habit. It is not the writer's desire nor his intention to continue this discussion, nor to bandy words or phrases with the editor, who will naturally take advantage of his position to have the last word and who is disposed to juggle with figures to meet his requirements. The writer has been accustomed to dealing with facts and of interpreting statistical data conscientiously; wherefore he does not feel qualified to cross swords (or pens) with the editor of the PRESS. Moreover, he has a very lively recollection of a charge once made against him by the present editor of the MINING AND SCIENTIFIC PRESS, who when shown the baselessness of the charge, apologized to the writer, it is true, but did not consider it necessary as "a matter of principle" to acknowledge his error to the superior officer with whom the complaint was lodged, and the *amende honorable* has, accordingly, never been made.

E. W. PARKER.

Wilkes-Barre, December 2.

[Mr. Parker is welcome to the "last word."—EDITOR.]

The Editor:

Sir—Mr. E. W. Parker, Director of the Anthracite Bureau of Information, in a letter dated November 6, published in your issue of November 25, criticizes the San Francisco Section of the Institute for the passing of a resolution based "entirely on *ex parte* evidence and on a matter with which it was not in any way familiar."

As Secretary of the San Francisco Section, I am somewhat familiar with the manner in which the Shockley matter was considered by the Special Committee and can

inform Mr. Parker that the Committee was familiar with the letters and telegrams of both sides of the controversy. These documents were sufficient to indicate the fact that the Board of Directors of the American Institute of Mining Engineers had ordered the management of the International Engineering Congress to delete from Mr. Shockley's paper certain statements based on published Government and State statistics.

Mr. Parker is evidently not familiar with the protest of the San Francisco Section, which has not attempted "to pass judgment upon a matter affecting a region and an industry with which it is not familiar," but has protested against the action of the Board of Directors in interfering with the professional right of one of the members of the Institute to express his opinion in the Transactions of the International Engineering Congress.

C. E. GRUNSKY, JR.

San Francisco, December 6.

Flotation at the Calaveras Copper Mine

The Editor:

Sir—In the article by Hallet R. Robbins appearing in your issue of November 25, I find the following:

"Without wishing to draw invidious comparisons, it is interesting to note that the National mill in the Coeur d'Alene, built to treat 500 tons per day of a simple chalcopyrite ore, cost \$153,000, and has never made so close a saving as the Calaveras plant, and cost about the same to operate as the latter with its present small capacity of less than 200 tons per day. Of course, much less was known about flotation when the National mill was built than today."

Certainly only to those who are not familiar with the different conditions surrounding the two mills that are compared could such comparison be considered "invidious." Mr. Robbins has started out to draw a comparison that does not compare, and leaves the impression that, in his opinion, what can be done in crushing and treating an ore under one set of conditions, and in one locality, should be duplicated under different conditions if the same talent is available.

The 'Mines Handbook' for 1916 describes the ore of the Calaveras Copper Co. as follows:

"Ore occurs in amphibolite schist underlying Mariposa slates, near intrusions of granodiorite, the *ore-bearing schists* ranging 100 to 200 ft. in width."

The same authority describes the ore of the National Copper Co. as follows:

"Ore occurs in a fault-vein in thickly bedded *white Revett quartzite*."

We hardly think that Mr. Robbins means us to assume that, in his opinion, white Revett quartzite can be reduced to the same mesh with as little expenditure of power, wear and tear, attention, etc., as would be required for schist. As a matter of fact, the white Revett quartzite at the National Copper mine was found to be of sufficient hardness to serve excellently for tube-mill

pebbles, and caused the most excessive wear on cheek-plates, liners, pebbles, and all wearing parts, that those connected with the construction and operation of the plant had ever experienced before, or since. Another point that should have been brought out, if a comparison were desired, is that the National Copper mill was built in 1913, before the development of the ball-mill to its present stage of usefulness. Had ball-mills been available at that time, they could have taken the place of the rolls and Symons screens in the dry-crushing plant, and the first series of Hardinge mills in the wet plant, materially reducing the cost of the mill, and the subsequent operating cost.

Mr. Robbins also states that the National Copper mill never made so close a saving as the Calaveras plant. In this he is in error. The National Copper mill-feed averaged 0.8% copper and often less. The tailing, during the later operations, averaged 0.02% copper. The saving, therefore, was closer, although, because of the extremely low heading, the percentage of copper per ton of ore was not so high.

As to the cost of the National Copper mill, this figures out at \$306 per ton of daily capacity, and includes excavations, concrete work, buildings, etc., as well as machinery and equipment. This price, considering the nature of the ore, the fineness to which it is necessary to crush, and the fact that the mill was built during a severe Coeur d'Alene winter, compares favorably with average costs under similar conditions. I cannot compare it with the cost of the Calaveras plant because I have not the necessary figures and facts to enable me to make such a comparison, and without these, I might reach erroneous conclusions and mislead your readers.

As to the pneumatic cells described and illustrated, these are, like several others, self-evidently an imitation of those used at the National plant, in which it is hard to see where the improvement comes in. One would have more respect for the cell illustrated if it had some points of originality.

Salt Lake City, December 2. ERNEST GAYFORD.

The Extra-Lateral Right

The Editor:

Sir—I have just read with interest Mr. Colby's article in your issue of November 11, and note a misconception in his allusion to the period during which extra-lateral pursuit of a lode was permitted in British Columbia.

I have not at hand all the old British Columbian statutes, and therefore cannot say just when extra-lateral right was first granted. The Mineral Act of 1884 certainly specifically afforded that right, and I myself am working claims possessing it, located in 1883, probably under the Act of 1882. To go back no further, it is plain that the right was permitted for at least ten years, and it required considerably more than the "brief period" mentioned by Mr. Colby (from the coming into force of the Act of 1891 to that of 1892) to establish the conviction in the minds of those concerned, that the evils

which have proved to be virtually inherent in the "old law" were greater than its supposed benefits.

Fortunately, I believe, the change of law was made before either British Columbia had become 'fashionable' with mining investors in London, Montreal, or New York, or any great number of claims had been staked. The Act of 1892, prescribing vertical limitation of mining rights was passed with but slight opposition, and the principle has become so thoroughly established, that we hardly realize that it has, without doubt, been accountable for the almost complete freedom from litigation concerned with underground trespass, enjoyed by claims located since the spring of 1892. It is an interesting and important matter of fact that the only two big lawsuits* arising from instances of underground trespass (whether alleged or actual matters not) which have been tried in British Columbia, concerned claims possessed of extra-lateral rights, and it is probably not far wide of the mark to assert that these two cases cost as much as all the other mining cases of the Province combined.

The increasing importance and present magnitude of the metal mining industry in B. C. are sufficient refutation of the dicta of those who, almost twenty-five years ago, had very clear visions of stagnation and decay, if not of disaster, following closely upon abolition of extra-lateral rights.

S. S. FOWLER.

Riondel, B. C., November 25.

Absorption of Gold by Plates

The Editor:

Sir—The absorption of gold by copper plates, mentioned in your editorial columns of November 18, is a matter of commercial as well as of technical interest, particularly to those who have to do with mills where plate-amalgamation is practised.

Figures are quoted giving the yield from the 'sweating' of old plates. The connection in which the term 'sweating' is here used is somewhat ambiguous. As "old plates" are mentioned, it is fair to assume that the plates were no longer in use and that it was intended to remove all the gold and amalgam from them that was possible. To do this, 'sealing' of the plates would have to be resorted-to, an altogether different process from sweating.

The actual procedure in the process of sealing varies in different regions. In some places in this country, plates are sealed by hammering and buckling the plate. In South Africa the plate is heated over a wood-fire to a temperature sufficient to volatilize the mercury. While still hot the surface is treated with strong hydrochloric acid and then with a saturated solution of ammonium chloride and saltpetre. After standing for several hours the plate is again heated to redness, whereupon the seal-rises and can be collected on cooling.

'Sweating,' as generally understood, consists in subjecting the plate in place to boiling water, or steam under

low pressure, and the removal of the softened amalgam by means of a wooden chisel or other hard scraper. In the treatment of plates to recover all the gold or amalgam, they are first sweated and afterward sealed.

At some mills the sweating is done at regular intervals, so that large accumulations of amalgam on the plates are obviated. In other places the opinion is held that plates which have been sweated do not recover their maximum efficiency for a while and that the loss occasioned in this way more than equals any gain derived from systematic sweating. There is something to be said in favor of this view, but the argument loses force as the accumulation of gold increases in value. Undoubtedly there are also cases where a considerable quantity of amalgam has been allowed to accumulate on plates, not as a result of the definite policy of the management, but simply because the extent of the accumulation was not known or suspected. In one instance within my knowledge a large amount of amalgam was recovered from plates after it had been decided to close-down the mill, and the large sum realized came as a pleasant surprise to both the management and the shareholders.

It will be gathered from the preceding remarks that the amount of amalgam which may accumulate on plates depends upon whether or not they are sweated periodically. The rate at which amalgam accumulates depends upon a number of factors, chief of which is the method of working the plates. This is seldom the same in different places. In South Africa and New Zealand it used to be common practice to keep the top half of the plates 'wet,' or soft, and the lower end 'dry,' or hard, these terms referring to the condition of the amalgam. The surface of the upper part of the plate was kept in a soft condition by the application of sufficient fresh mercury at each dressing. At the daily clean-up all the amalgam that could be scraped together with a light iron scraper from the soft portion of the plate was collected. A portion of this was cleaned on the plate by washing with water from a hose and mixed (to the proper consistence for rubbing on the plate) with fresh mercury. This was then rubbed into the plate with a blanket swab. The lower or 'dry' portion of the plate was dressed by rubbing heavily with a canvas pad. No amalgam was taken off this part of the plate and it was not usual to apply fresh mercury, the surface being kept in the right working condition by absorption of the mercury draining from the upper part of the plate during operation. At the larger of the mills of the Waihi company in New Zealand it used to be the custom (amalgamation has now been discontinued in favor of all-cyaniding) to steam the hard amalgam on the lower half of the plates at the rate of two plates per week, and as there were 15 plates, each plate was treated thus about once every seven weeks. The portion of the plate to be steamed was covered with canvas stretched on a light wooden frame leaving about three inches between the canvas and the surface of the plate. Steam from a hose connected with a boiler was forced, under this canvas frame for 30 to 60 minutes, according to the supposed extent of the accumulation.

*Center Star v. Iron Mask, and Star M. & M. Co. v. Byron N. White Company.

The plates were of Muntz metal and it was necessary to exercise some care in order to prevent buckling and cracking of the plate by keeping the steam-pressure low and not allowing the jet to impinge directly on the plate. The scraping operation took two men about 30 minutes per plate and was done with wooden chisels having a steep edge. The amount of steamed amalgam obtained in this way from two plates was approximately 1000 ounces. The total recovery of gold by amalgamation was approximately 23% of the total gold content. The gold was finely and evenly distributed through this ore and was never visible to the unaided eye.

This system of working the plates was particularly well suited to the ore at Waihi, where it was not sought to obtain the maximum recovery possible by plate amalgamation, but rather to recover the more easily amalgamable gold, leaving the finer gold to be recovered subsequently by cyanidation. In other places hard amalgam is not intentionally allowed to accumulate in the way described. Usually the entire surface is kept soft, and scraped as closely as possible at each clean-up. If an iron scraper is used for this purpose the accumulation of a large quantity of amalgam may be prevented, but if only india-rubber scrapers are used, a skin of hard amalgam will continue to form until removed by the sweating of the plate. This, in some instances, may not be done until the plate is no longer required for amalgamation.

It will be gathered from the foregoing that the amount of amalgam accumulated on plates, recoverable by sweating, cannot rightly be considered as a factor of the tonnage, nor yet of the time involved in its accumulation, but that it is altogether dependent upon local circumstances and expedience.

After plates have been in use for some time (unless special care has been taken to prevent it) a scale of hard amalgam forms on the surface of the copper. This is not easily removed by sweating, being difficult to soften on account of the small proportion of mercury in its composition. Such a superficial scale can be removed only (and not completely even then) by scaling. It is the gold in this scale that is generally said to have been 'absorbed,' but this is an instance of incorrect terminology, for it has been conclusively shown by investigators that neither mercury nor gold is absorbed by the copper in the sense that it soaks into the copper plate, but that it exists, as already stated, as a scale on the surface. Stanley's investigations in South Africa* have shown that 99% of the gold remaining after sweating is in the top or surface layer, 0.02 inch thick. He showed further, by microscopic examination of sections of a plate, that the little gold remaining existed as a filling in minute pores and blow holes in the copper into which mercury carrying gold in solution or suspension had percolated. Richards† also investigated this matter and showed that the amount of gold below 0.01 inch was negligible.

The amount of gold left on plates after careful sweating has been variously recorded as 8 up to 45 oz. per plate. This depends upon the thoroughness with which the sweating has been done and also on the condition of the surface of the copper of the plate. The surface of very old plates becomes covered with inequalities that make it difficult to remove the hard amalgam. If the operation of scaling is performed carefully, the value of gold left on the plate is negligible, and certainly would not pay for further treatment. Much less would it be worth while, as was the old custom, to send it to the smelter, save for its copper value.

WILLIAM MACDONALD.

Berkeley, November 22.

RUSSIAN PETROLEUM PRODUCTION, prices, and shipments from January to April inclusive, show points of special interest. The period covered by the statistics is unusually recent to appear in so careful a study; the detail in which the returns are given suggests an authentic source, possibly the official figures of the Petroleum Convention itself, and the picture of the whole industry which even the colorless figures of the review suggest, shows both depressing and stimulating effects which have resulted from war-time conditions. In spite of a greatly increased demand for oil-fuel, due to interference with the usual coal supplies, the total production of petroleum in the whole Empire for the first third of the year showed a decrease of three million poods (1 pood = 36 lb.) in comparison with the same period of 1915, thus continuing the decrease in output which has been marked for several years past. Apart from influences previously active, this decrease may be in some degree due to shortage of labor and materials, and difficulties with transportation such as would naturally arise from the War. Marked increase of production during April 1916, amounting to 2.1 million poods in comparison with April 1915 (most of the increase occurring in the Grózný and Surakhán fields) shows on the other hand that the stimulus of the War markets has taken effect. It seems reasonable to expect that for the whole year the total output of the Empire will be considerably larger than that for 1915. *Russia*, published by R. Martens & Co., Incorporated.

FIBROUS STRUCTURE in minerals is thus explained by Dana, in his 'Systematic Mineralogy': "When a solution is spread thinly over a large surface, minute crystalline points enurst the whole, and if the solution be gradually supplied, as crystallization goes on, it is obvious that the minute points may elongate into crowded prisms of fibres, producing a fibrous structure. Such a structure is common in narrow seams in rocks, and the fibres are usually elongated across the seam." Chrysotile is an excellent example of this type of structure.

†Ore Dressing, by R. H. Richards, Vol. 2, page 76.

DIVIDENDS paid by the Broken Hill Proprietary, Australia, during its last half-year were \$580,000, making a total of \$61,135,000 since 1885.

The Prevention of Misfires

By E. F. Brooks

Blasting, or breaking of ore and rock, constitutes a large item of expense in mining, and any reduction of this expense is always welcomed. One way of reducing cost would be to lessen the number of 'misfires' or missed holes, as they are commonly called in the mine. Precautions may be taken to reduce them to a minimum. They are sometimes caused through poor judgment in placing the holes, the first hole to be fired breaking to a joint or cleavage-plane, tearing off the collar of some other hole, and with it the fuse, causing a 'miss.' No inflexible rule can be given for placing a round of holes, as this depends entirely on the character and hardness of the ground to be broken. The machine-man must use his judgment, which only becomes ripened through experience. The fuse should always be of the best quality, whether in wet or dry ground. A poor quality of fuse is dear at any price; the best fuse is always the cheapest, as one misfire, due to poor fuse, particularly in hard ground, may result in more damage than the cost of several cases of good fuse. The same applies to detonators, or caps. The best results are obtained by using high-power caps, 5X or 6X. In the case of gelatine powder, it frequently happens that a 3X or 4X cap may still fail to explode the charge, merely setting the dynamite on fire, causing a 'burnt hole,' which is worse than an ordinary 'miss,' owing to the resulting noxious fume, which is more poisonous to inhale than the fume from powder that has exploded properly. A 'burnt' hole, in the absence of good ventilation, usually means a headache for the next shift.

Nothing weaker than 5X or 6X caps should be used. Misfires may be caused by not using proper care in cutting or 'spitting' the fuse, so that the holes will go in proper succession, the hole that should be second or third sometimes being the first to explode, possibly tearing a portion off the collars of the holes that should have preceded it; pulling out or cutting off fuses and resulting in one or more 'missed holes.' If in hard ground, such a result is likely to spoil the whole round, leaving in the face holes of varying depth, called by miners 'old bottoms,' 'old guns,' 'boot-legs,' and so forth, each containing from one to four or more sticks of powder, and constituting a menace to those who have to work later, whether the men of the same shift or others.

Another occasional cause of missed-holes, and one I have never known miners to take into consideration, is tamping. Many years ago, when black powder was the explosive used, it was necessary to tamp holes, and tamp them firmly, using a wooden or copper rod, and a hammer for the purpose. This is unnecessary in the use of nitro-explosives, as even the air itself will offer sufficient resistance to exploding dynamite to constitute good tamping.

It is a common practice with most miners to use some kind of tamping. Sometimes fine rock, or dirt, is thrown

in the hole, and rammed with the loading stick; at other times balls are made of clay or gouge, and firmly rammed, which is even worse than using fine rock, for the reason that the side-spitting of the fire in the fuse will sometimes set fire to the powder, which, while it does not explode, will generate sufficient gas to force the tamping out of the hole, drawing the fuse with it and leaving another 'missed hole.' Had there been no tamping used, even if the powder took fire and burned faster than the train of powder in the fuse, it would explode the charge as soon as the fire reached the cap.

I would suggest that in holes pointed downward, a handful or two of fine dirt be thrown into the hole, but not firmly tamped, using this as a safeguard against accidents when firing or 'spitting' the holes, such as the accidental dropping of a lighted candle into the hole, or dropping the lighted end of a fuse into it.

Many times 'reports short,' or 'misfires,' are traceable to carelessness, or to the nervousness, due to inexperience, of the man 'spitting' the round of holes. In his haste to leave, the miner overlooks some of the fuses, and so fails to spit them. Evidence of this is not infrequently found in the broken rock—a fuse with cap attached—which, upon examination, shows that it never had been lighted. A fuse cut to proper length will give the miner abundant time to reach a place of safety.

In blasting under water or in wet ground, it is absolutely necessary to see that the point of union between fuse and cap is waterproof. This may be accomplished with a good pair of crimpers, properly used, without the use of any waterproof substance, such as axle-grease, which is so commonly used for this purpose. However, it is generally safer to employ some kind of waterproof substance. But axle-grease, or anything containing coal-oil, is not recommended, for, if left too long, it will penetrate the fuse, and possibly cause a misfire. There is on the market, and handled by most dealers in powder, a preparation made for this purpose that is more reliable than most kinds of grease or wax.

The kind of crimpers used is largely a matter of preference. I prefer those making a groove around the cap. Make a double-crimp, turning the fuse slightly after making the first crimp, and take care to crimp close to the joint between the fuse and cap, but never close to the fulminate in the cap, for if crimped too close to the fulminate the flash from the little powder remaining in the fuse between the crimp and fulminate may not be strong enough to explode it, while if $\frac{1}{2}$ in. or so of fuse is left below the crimp, the force will be sufficient even if tightly crimped. Care should be taken to see that the diameter of the fuse is just slightly smaller than the shell of the cap, for if too tight, the crimper will compress the fuse so tightly that the fire may fail to pass the point of compression, when there is created another cause for a misfire. By observing the foregoing suggestions, with ordinary care the miner will reduce to a minimum the chance of having 'missed holes,' and instead of being the rule, they will become the exception. Above all things do not use the teeth for a crimper.

ON THE WAYS

TO THE FAR SIDE OF THE POND

YUBA DREDGE, No 15

LOOKING EAST No 15 DREDGE

The Launching of the Yuba No. 16

By Walter E. Weeks

The reasons why the PRESS selected me to 'cover' the launching of the 'Sweet Sixteen' of the Yuba Construction Co., built for the Yuba Consolidated Goldfields Co., may be enumerated as follows:

A new Graflex camera.

An amphibious Ford.

An invitation to a turkey dinner at the construction camp at Marysville.

The band played, the whistles blew, the flags waved, and everybody cheered as the great black hull slipped smoothly into the muddy pond, driving a curling wave before it which rocked shoreward until it broke against the hills of tailing.

I stood on a bit of an island in the pond, and it was hard to realize that I was not in Kennebunkport, Maine, watching the good ship *Mary Jane* take her maiden dip.

The new dredge seemed anxious to be about her stupendous task, for she could not wait to have all of her triggers sprung, but started down the ways crushing the two inside 4 by 4 timbers that tied her to the land. Down she went with a dignity comparable only to the precession of the equinoxes and glided majestically to the farther side of the pond. Then a rope was rove about her taff-rail and a tiny Yuba tractor like Ulysses was called from the plow to pull her back to shore. But the good ship, as if resentful, snapped the line. She was finally subdued and now floats meekly at her berth while the various appliances that are considered good form in gold-dredge construction are heaped upon her. When finished she will weigh 2700 tons, will have buckets holding 18 cu. ft., able to dig to a depth of 84 ft., and with a monthly capacity of 350,000 cu. yd.—all at a cost of half a million dollars.

But why, you may ask, do I not give the size of her waist (nautical term) and other useful and entertain-

SECTION OF DREDGE HULL AND WAYS BEFORE LAUNCHING.

ing dimensions. It is because with the exception of the tailing-stacker she will be almost a duplicate of her sister boat No. 15, which has been thoroughly described. The picture shows No. 15 in her present position. No. 16 will have two tailing-stackers each 220 ft. long, placed at the stern, but stacking one to each side. This construction has been adopted to comply with the mandate of the

Débris Commission that a 1000-ft. channel shall be left through the dredging field. No. 16 will dig one-half of this channel and a later boat will dig the other half.

The accompanying sketch shows where dredges No. 14 and 15 are working. No. 16 will enter the field at A and, working down-stream, will remove the virgin ground between the two piles of tailing left by No. 14

MAP SHOWING PRINCIPAL DREDGING DISTRICTS OF CALIFORNIA.

THE NEW BOAT WILL START DIGGING AT A.

and 15. The ground will be excavated in two cuts, each about 250 ft. at the surface. When No. 16 is taking the right-hand cut the starboard staker will pile the tailing on those already left by No. 15, and when she is taking the left-hand cut the port staker will pile the tailing on that left by No. 14. In this way an open channel 500 ft. wide will be left through the dredging ground. Another 500-ft. channel will be dug by a later dredge to the north of the tailing-pile left by No. 15, giving a total width of 1000 feet.

The bottom photo of the group shows the virgin ground between the two tailing-piles. The picture is taken looking east. No 15 dredge is on the left.

In 1915 Yuba county held third place in rank of gold producers, being exceeded only by Amador and Nevada. It holds the leading position in production of placer gold, by reason of its gold-dredging activities. The output of the county in 1915 was 130,792 fine ounces of gold, valued at \$2,703,710, and 10,363 fine ounces of silver. There were 12 dredges in operation in the county in 1915.

Conditions in Mexico

By Our Mexican Correspondent

It is curious that Carranza's banking decree of September has not caused more comment in the United States. Aside from a protest made by the diplomats representing European powers before the United States-Mexican Commission, nothing seems to have been done to enlighten the American public as to this bold pronouncement, which may prove later to contain more international political dynamite than all the other Carranza decrees put together. A condensed translation is as follows:

"V. Carranza in use of the faculties of the Executive Power of the Nation, and considering:

(1) That the Executive Power is under obligation to fulfill the Constitution and is competent to abrogate unconstitutional laws and concessions.

(2) That the laws which establish banks of emission, allow them the privilege of emitting notes in excess of their metallic reserves without paying any compensation to the Nation, and permit them to cash in their mortgage credits without a judgment, and exempt them from taxation, are unconstitutional. Because Article 28 of the Constitution declares that there shall be no monopolies under the guise of protecting industry; and diverse rules of the Constitution prescribe that laws must be applied equally to all litigants, and that none may enjoy advantages except in return for public service. Also it is forbidden to restrict the States by exempting banks from local taxation.

(3) That the application of ordinary law to banks might bankrupt them and bring back the financial crisis, besides giving rise to many legal questions to the injury of bank investments that should be protected by the State, even though the banks were created under illegal franchises and laws.

(4) That the bankruptcy of enterprises entrusted with public services requires the naming of Boards of Receivers (*Consejos de Liquidacion*) who may take charge of the disputed interests. In the present case, it is convenient that, for the management and liquidation of the banks, legal representatives of all interests should take part.

Thus I have decided to decree:

Art. I. There are abolished all laws giving franchises to banks of emission; and the corresponding part of the general banking laws of 1897 and 1908, by which these banks have the monopoly of note issues, and are allowed to follow unusual procedures in judicial actions, and are exempt from taxation.

Art. II. There are allowed to banks of emission a period of 60 days from date in which to increase their metallic reserves enough to pay all their notes in circulation.

Art. III. After today, the said banks can only do business when authorized by the resident inspector (*interventor*) of the Treasury (*Hacienda*), and of a sort to protect the bank's interests.

Art. IV. The Secretary of Hacienda will at once proceed to name for each bank of emission a Board of Receivers, which will consist of a member of the Commission of Bank Inspection, a bank inspector, the bank manager, and a representative of the creditors. The latter's place will at first be filled by the National Procurator, or a specially designated agent of the Federal public ministry; but when the bank's creditors have met and selected, under material seal, a representative of the majority of its creditors, and so notified the Secretary of

Hacienda, the place of the temporary incumbent will be filled by the latter. The member of the Commission of Bank Inspection will be president of the Board of Receivers and have the decisive vote.

Art. V. The Board of Receivers will have the following powers: (1) Watch over the conservation of the specie. (2) Perform all kinds of operations whose object is to preserve the bank's interests. (3) Liquidate the bank, after getting permission of the Secretary of Hacienda, or in obedience to orders from him in case the bank does not increase its metallic reserve according to Art. II of this decree.

Art. VI. The Secretary of Hacienda, ex-officio or on request of an interested party, will decree all those measures that may appertain to the protection of the bank and to the action of the Board of Receivers.

Art. VII. The banks cannot be declared judicially bankrupt without permission of the Secretary of Hacienda.

Art. VIII. The distribution of the specie reserve of a bank can only be effected according to the orders of the Secretary of Hacienda.

Art. IX. In case of non-judicial liquidation, there must be observed, except for a law to the contrary, the graduations established by the common law for credits.

Art. X. The banks that comply with Art. II of this decree will be free from receivers, but will be subject to existing legislation in everything not contrary to this decree. Constitution and Reforms. Given by V. Carranza in Mexico City, September 15, 1916, to R. Nieto, sub-Secretary of Hacienda.

To get the proper perspective of this decree, I shall review recent events in Mexican finance. The wholesale repudiations, in June, of the old Carranza notes (published in the PRESS of July 15) failed in their object of validating the new 'infalsifiable' notes. The mere decree of the obligations of a debtor, if accomplished by dishonorable and violent means, will not increase the market-value of his remaining obligations. This statement applies to either public or private debtors, and its truth was never better demonstrated than by the fate of the infalsifiable notes after the 'massacre' of their predecessors last June. By August 1, three months after their debut, the new peso notes had dropped from their nominal value of 10 cents (U. S.) to 43c.; by September 1 they were down to 33c.; by October 1, 3c.; and by October 28 to 1.8 cents. Their present official quotation is 1.4c., and as the old notes are still receivable for a few public dues such as railroad fares at one-tenth their nominal value, this makes the value of the latter a tenth of 1.1 cents, or 0.14c. Thus the old notes are now officially declared by Carranza to have a value of only 1/360 of their nominal value of 50 cents, a record in depreciation that beats the famous example of the French Revolutionary *assignats*. Yet it was only last March that Carranza decreed the old notes to be "sacred obligations of the Nation," which could never, in honor, be redeemed at less than par.

The collapse of the new paper money during the sum-

mer aroused discontent in the army. Though the common soldiers were advanced from ₧2.50 to ₧3 per day, this had little effect, as all prices had long been approaching a gold basis. On the northern frontier and in the capital, the troops were kept quiet by giving them rations in addition to their wages, but elsewhere, where this was not done, various things happened. In the country, the soldiers took to foraging for a living more actively than before, and few were the Zapatistas of the animal kingdom, such as poultry, pigs, or lambs, that escaped their hungry maws. In the cities, a troop could often better its condition by deserting bodily from one barrack to another; and, as the Carranza military organization is not centralized, but Federal, there was nothing to prevent an ambitious general from thus increasing his forces at the expense of his rivals.

The peninsula of Yucatan has been protected by its isolated position from the ravages of revolution, and has been fortunate in its Governor, the energetic and progressive General Alvarado. This State enjoys a big income from the *henequén* (hemp) industry, and its soldiers are paid so well in coin that were it not for the expense of the long journey, it is likely that not another Carranza general in southern Mexico could hold his troops against the superior attractions of the Yucatan service.

Early in September Cabrera decreed a *ley de pagos* (law of payments) that attempts to adjust debts unpaid or not yet due, in terms of the infalsifiable notes. It divides financial time into four periods, namely: (1) Normal, or when money was at par, before April 15, 1913; (2) from April 15, 1913, to September 30, 1914; (3) from September 30, 1914, to April 30, 1916; and (4) from April 30, 1916, to date.

During the first period, debts will be based on silver and may be settled in infalsifiable notes at a ratio of 5:1. During the second period debts will be based on bank-notes and may be settled in infalsifiable notes at ratio of 4:1. During periods No. 3 and 4, all debts will be based on Government notes and may be settled in infalsifiable notes at par. To this practically the only exceptions are debts payable in foreign money, which must be settled only in such money or its equivalent in Mexican gold. A curious feature is the regulation that allows certain favored classes of creditors to postpone for a year the agony of a payment in infalsifiable notes. Among these are charities and city councils, also the legally incompetent, the aged and invalids, provided only their capital is under ₧20,000 gold. Evidently any creditor, however crippled or ancient, who is enough of a plutocrat to own ₧20,000 gold has put himself beyond the pale of this precious *ley de pagos*.

As debtors had cheerfully been robbing their creditors with legal sanction ever since 1913, the new Cabrera decree did not cause much havoc; for creditors had already either lost their money or ceased to make loans. As it assumed a value of 10 cents (U. S.) for the infalsifiable peso, when its market-value was only 3 cents, the absurdity of the regulation was almost visible to the aver-

age Mexican—who is quite devoid of any mathematical sense. Soon, perceiving its practical uselessness, Cabrera decided to ignore it, as he has already ignored so many other of his progeny of still-born flats, and to proceed on a new tack, leading to speedy specie payments. In October it was decreed that all labor should be paid in coin at the rates of 1912, beginning on November 1; but later the Department of Fomento modified this decree by allowing 40% of wages, for rates under ₧1.50 daily, and 50% of wages, for higher rates, to be paid in infalsifiable notes until January 1, 1917. As there is scarcely any coin in circulation, the coin portion of wages can be paid in paper at the official rate, which is changed every 10 days, and was 25:1 on November 1, and 35:1 on November 10. All railroad charges, as well as national and local taxes, began to be collected on a gold basis on November 1, and mail-rates, payable in paper, were quadrupled on that date.

On the first decennial pay-day of the new system, on

November 10, the common soldiers were paid-off at a rate of 50 centavos in silver plus ₧1.50 paper per day, and officers proportionally higher. Few in the Civil Service fared as well, as most of them only got the usual Government notes as pay. Similarly, many factories were unable to meet the new exactions as to payment, and their men therefore went on strike. It took the United States from 1865 to 1878 to effect a resumption of specie payments, and it seems to be beyond the power of even Luis Cabrera to effect this change in three months. Of course, import duties could at once be collected in coin, but the collection from real-estate owners and merchants in November of just 25 times the direct taxes they had to pay in October is entirely another matter. Therefore most of the local taxes remain unpaid, and along with them the increase in the salaries of Civil officials. However, many of the latter are not suffering on this account, for, as the history of Turkey and China proves, an official may often wax rich on pauper's pay. It is a peculiarity of what little morality there is among Mexicans that it is a strictly private affair; thus an official who personally might be stainless, would work cheerfully and without a word of criticism beside the most flagrant of rogues. This national trait makes it improbable that Mexico can ever attain a civilized government from within, for few are the decent Liberals in Mexico who are not now working, without a word of protest, as aid to one of the most heartless rings of spoilers who ever had control of any modern country.

In 1912 there were 20 odd banks of emission in Mexico, mostly chartered by Limantour in 1897 and named from

the State where the main office was situated. These banks were authorized to issue notes and loan them on commercial paper up to double the quantity of their metallic reserves. Two banks only, the Nacional and the Nuevo Leon, were allowed to issue notes to thrice their reserves. Huerta was the first ruler to tamper with the banks; in 1913 he allowed them to suspend specie payment, and in 1914 he permitted them to expand their issues beyond the legal limit in order to grant him a forced loan of P50,000,000 in bank-notes. These measures began the decline in the value of Mexican pesos, which were quoted below 30 cents in July 1914. As explained in my letter published in the *PRESS* of January 29, the banks have long abandoned their usual functions and have only been kept open to handle a fraction of their former discounting operations. Though it has been their policy since 1914 to retain all bank-notes taken in, and to pay out only Government notes, there is still outstanding a great quantity of bank-notes, most of which are probably hoarded by the native middle-class, who were unable to get enough coin to embody their savings when the deluge of Government paper drove them to burying their fortunes.

Cabrera first tackled the banks a year ago, just after Carranza's recognition by the A. B. C. and B. U. G. conference, but as the attack depressed the value of Government notes, and seemed to be of no public advantage, he abandoned it after merely revoking the charters of a few of the minor banks. But this year, Cabrera has been compelled by his dire need to resume the bank-baiting game. His issue of infalsifiable notes is a complete failure, and the Mexican masses are now too well enlightened as to the paper-money fraud to permit the success of any more fiat currency. The only exit to this blind alley is the path of specie payment, and the banks have the specie.

In September, the acting-Secretary of Hacienda, R. Nieto, decided to intervene only the two largest banks of emission, the Nacional and the Londres of Mexico City. Nieto promised the other banks that he would not disturb them under the September decree until after October 31. But the managers of the two intervened banks proved lawless and stubborn, they refused to open their vaults, and were accordingly sent to jail; so Nieto determined to temporize no longer with anyone, and, withdrawing his promise, he intervened all the doomed banks early in October. The custom of Mexican banks is to divide the secret of the vault's lock among several persons, whose united efforts are therefore essential to open the combination. Faced by this obstacle, Nieto is making slow progress, though he has finally managed to open the Nacional and the Londres banks. A mere jailing of the recalcitrant bank-officials seems a feeble measure in view of the public need, and either a torture of the officials or a dynamiting of the vaults seems the only alternatives to quick fulfilment of the decree. It is planned to get from the loot of all the banks some 80 million pesos, and before this is spent Cabrera hopes that fortune will again direct him to some fresh store-houses of

coin. Should Wall Street still remain deaf to his appeals for a loan, there are still untapped reserves among American pacifists; thousands of these worthy people will undoubtedly only be too glad to invest the bulk of their fortunes in Mexican bonds, if only given the chance, in order to assist such a pacifist hero as Carranza.

The wholesale spoliation of Mexican banks may alarm some American statesmen, for fear that later, under the Monroe doctrine, the United States may have to reimburse the stockholders and depositors, mostly Europeans. That this fear is baseless has been shown by Ing. Rolland, editor for the Latin-American News Association of New York, which is busily circulating booklets in English to explain the Carranza government's doings to Americans. In an essay entitled 'Intrigues of Clergy against Monroe Doctrine,' Rolland says: "The capital placed at interest in Mexico is, by more than 80%, the property of one creditor only, the clergy. And the clergy within Mexico has Europeanized its interests. How? By making laws in the name of European bankers and pretending that the capital which supports and gives life to business here is capital belonging to the clients of said bankers, the savings of Frenchmen, Englishmen, Belgians, etc."

The agitation of the Mexican question in the recent presidential campaign in the United States seems to have done little beyond confusing the voters' minds. To be a good Republican, one had to approve of Henry Lane Wilson and of the recognition of Huerta; to be a sound Democrat, one had to defend with unctious all the countless blunders of President Wilson in Mexico since 1913. The prevailing ignorance of facts is shown by no one nailing the error of Senator La Follette, when he affirmed that Americans own in Mexico a third more property than the natives, 1057 millions against 793 millions, while all other foreigners only own 582 millions. La Follette took his figures, heedlessly, from Letcher's U. S. Consular Report of 1912, without stopping to consider how all the property of an industrial nation of 15,000,000 could only be worth 1932 millions of dollars or \$129 per capita, as compared with about \$1500 per capita in the United States. Figures don't lie, but surely liars do figure! It is probably little known in the United States what an influence the help of Carranza exerted for the re-election of Wilson.

The many Mexicans who were boldly "interfering in the internal affairs of the United States," by preaching for Wilson, met with little or no opposition, for the few former residents of Mexico, who alone had the knowledge to expose their yarns, did not care to lose their holdings in Mexico by attracting Carranza's adverse attention. The one-sided nature of the friendship for Woodrow Wilson was never better exhibited than in what happened in September to Burton Wilson, a lawyer of Mexico City and president of the American Club. The latter had directed to the United States-Mexican Commission a short history of Carranzaism in Mexico. On being confronted with this history by the American members of the Commission, Cabrera refused to con-

sider it until he was told the name of its author, whom he guaranteed immunity from any harm. Within a week this American viper was arrested and ejected by Carranza from the bosom of his outraged Mexico. On being blamed for this breach of faith, Cabrera merely shrugged and deplored the fact that his superior powers had not allowed him to extend the promised protection. A side-light on this incident is the recovery, by Burton Wilson's expulsion, of a palace long coveted by Carranza's 'Commission of Intervened Property.' The palace in the Colonia Roma of Mexico City belonged to Huerta's ex-minister Lic. Vera Estañol, who had rented it in 1913 at a low figure to his friend Burton Wilson, and the latter had for over two years succeeded in holding it against the attempts of the Commission to eject him. This Commission has had as many as 1000 houses and estates intervened at one time in the Federal district; but as it operates in secret and gives no public accounting of the 'reactionary' property in its charge, and the original owners are mostly in exile or in jail, it attracts little public comment.

Some events in August have strained to the breaking-point what once gave promise of becoming a touching international labor friendship. I refer to that between Gompers, president of the American Federation, and Carranza, erstwhile patron of the Mexican I. W. W. Last June it was perhaps more due to the pleading telegram from friend Gompers than to anything else that Carranza held his hand from exacting stern retribution on the U. S. Army for the Carrizal massacre. But in August, the labor-unions comprising the men working on the electric trains and power-supply of Mexico City—operated by Carranza—struck for the payment of wages in coin and announced the event by shutting-off all the current in town. Reversing the procedure of Wilson in the Adamson episode, Carranza, instead of being held-up by the labor leaders, clapped them in jail and gave them 48 hours to die or else stop the strike. It stopped, but so apparently has the international friendship.

As the leader of this strike, the anarchist genius, Dr. Atl, was arrested and condemned to be shot; but he appealed to his original Carranzista patron, General Obregon, and through his protection was enabled to escape to the United States, after a very close call. The fact is that Dr. Atl has been an eyesore to Carranza for some time, his labor doctrines had become as out-of-date as a last year's bird-nest, and in his editorship of the important Government daily, the *Acción Mundial*, he had allowed a passion for literary sensations to lead him often to the brink of the precipice of *lèse majesté*. What a mine for the inner history of the Carranza ring Dr. Atl might prove if he would open his heart to some enterprising American journalist! Carranza may yet regret his action; tyrants have been ruined ere this by cast-off servants of far less ability and audacity than Atl.

The famine predicted in my July letter probably caused less mortality than then seemed likely. But this outcome was due chiefly to having this year more favorable rain than in 1915, enabling the harvesting of 60%

of the normal crop. In June many places were without food, and in San Luis Potosi it was only the prompt action of the Governor in importing a train-load of grain from Michoacan that saved the city from decimation. However, the governors along the west side, from Leon to Zacatecas, were less energetic and lost thousands of their subjects from famine and its resultant typhus. The famine was aggravated between Guanajuato and Queretaro by some July cloud-bursts, to which was ascribed its entire origin by the official press-notices, but its real cause everywhere was not water, but two years of dosing by old Dr. Carranza.

There seem to be just as many Zapatistas as ever in southern Mexico, where Carranza has never held more than the cities and the railroads. When Pablo Gonzalez captured his capital, Cuernavaca, last May, Zapata merely shifted his headquarters to a valley farther east. During the summer, there was a lull in the combats between 'liberators,' but not because of any culpable decrease of zeal. The obstacle was the scarcity of cartridges due to the United States embargo, in force since April. What Carranza now wants most of all is his new cartridge factory, detained by the embargo; for with this factory he can provide cartridges by merely filling old shells with fresh powder, and can then feel independent of expensive new American cartridges. One would fancy that Zapata might have cartridges even if Carranza hadn't, but he would be wrong, for Zapata relies mainly for new cartridges upon their capture or purchase from Carranza officers. However, evidently tired of inaction, Zapata, a fortnight ago, posted notices all over his territory, warning travelers to beware of Carranza trains, as he expected to begin blowing them up. That this was no idle threat was soon demonstrated by the wrecking of the Mexicana railroad tunnel at Maltrata by the artificial collision of two trains, while on November 10 the Interoceanic train was derailed at Banderilla near Jalapa, and many passengers were killed.

As yet Carranza has shown no signs of abrogating his decree of last year, which forbids the sale of Mexican real estate to foreigners, though this decree was promulgated ostensibly as a temporary measure to protect simple native land-owners from the decoy of a depreciated fiat currency. Many of these simpletons are being made to pay dearly this year for protection, for they can only safely harvest their crops by agreeing to give 50% of them to the local general. Just before harvest, one 'honest' Carranza general bought a big ranch, whose crops had been cultivated by villagers on shares. But the new owner harvested all the crops for himself and the villagers found themselves with nothing for their pains.

GOLD received at the San Francisco Mint during November totaled 667,239.777 fine oz., and 1,115,453.45 oz. of silver. Coinage consisted of 5,400,000 dimes, 3,600,000 nickels, and 4,920,000 cents. The vaults contain \$426,173,268.95.

Gold in Silver Concentrate

By A. J. Sale

When concentrate carries three or four hundred ounces of silver and but one or two-tenths of gold, the assayer may have some difficulty in making an accurate gold determination. When a silver button contains less than 0.05% gold, the parting leaves the gold in such a state of division that, even if it does not 'break,' it has a tendency to adhere to the annealing cup. I have worked out the following method, which gives an accurate gold determination, even with the highest grade of silver concentrate that has ever come within the range of my personal experience:

Weigh an assay-ton of the pulp and place it in a clean clay crucible. Have the muffle at not quite red heat. Hold the crucible on its side and with a few light taps cause the pulp to distribute itself uniformly in the crucible. Carefully place the crucible near the mouth of the muffle and allow a full draught of air to pass through. After about 20 minutes' roasting, remove the crucible from the muffle and tip it the other way, so that the bottom layer of the pulp becomes the top. Roast 10 minutes longer, then take out and allow to cool. If the roasting is performed with care, the pulp will not matte or cake, and will not need re-grinding.

On top of the roasted pulp put a charge consisting of 25 grams bicarbonate of soda, 30 gm. litharge, and 12 gm. borax-glass. Mix, with a spatula, as much as possible in the crucible; then dump into a cloth and roll until thoroughly mixed, being sure to pulverize any lumps that may be present.

After mixing, the assay is given a cover of borax-glass and fused in the usual way, using a low heat at the start. A few trials will be sufficient to determine the exact time of roasting necessary to give the proper-sized lead button. Cupel as usual.

After cupelling, the silver button should be hammered flat and placed in a small porcelain crucible half-filled with 1:10 nitric acid. The acid is heated, but not allowed to boil.

When the action has proceeded so far that but few bubbles are being liberated, the gold button should remain intact, but will probably be swimming around on account of its spongy condition. When this stage has been reached, most of the acid may be drained off by holding against a stirring rod.

Cut a disc of lead-foil about an inch in diameter, and shape it into a small dish by pressing against the thumb. Into this dish carefully wash the almost parted gold button. Allow to settle, and drain off as much of the water as possible. Dry at a low heat, being careful that it does not 'spit.' When thoroughly dry, wrap the button in another piece of lead-foil; cupel; flatten the small silver button; part; anneal, and weigh in the usual manner. The lead precipitates the proper amount of silver from the nitrate solution to make a good separation of the gold, and the final button, while small, will be in compact form.

Recovering Gold From Saprolite

The saprolite of the southern Appalachian mountains is merely the much decomposed country-rock, principally schist and slate of various kinds. It is a name applied to thoroughly decomposed 'rotten' rock that is still in place. The composition is variable. In some districts the saprolite is gold-bearing. Rock of this description, particularly the red kind, was formerly called 'laterite.' In such rocks the gold occurs in the schist and in veinlets of quartz traversing it in every direction. Pyrite usually is found in the schist, particularly in close proximity to the quartz veinlets. It has been found desirable, if not actually necessary, to remove the hard lumps of mineral from the soft decomposed rock when attempting to recover the gold. These lumps consist of quartz and other hard rocks, in pieces ranging in size from an inch to a foot in diameter. Garnet also is plentiful in some localities. These hard lumps are removed by running the material, mixed with about an equal weight of water, through trommels having holes from $\frac{1}{2}$ in. to $1\frac{1}{2}$ in. diameter. The soft portion passing through the trommels goes to a 'washer' where the clayey earth is dissolved and the gold brightened, so that it will amalgamate readily. It is the practice to disintegrate the gold-bearing material before it reaches the trommel, and to accomplish this it is run through an iron-lined sluice, 50 ft. or more in length, set on a grade of 3 in. to the foot.

There are two types of washer used—high-speed and slow. The high-speed washer disintegrates the pulp by the beating of propeller-like blades on a revolving-shaft, which push the pulp forward up-grade to the discharge. Two of these machines comprise a set, and are arranged tandem. The first one, 18 ft. long, has a grade of 3 in. in its length, the shaft revolving 200 r.p.m. The second washer is 12 ft. long with a grade of 2 in., the shaft revolving 260 r.p.m. A screen follows each washer, the first of which removes oversize rocks, roots, and any other foreign substances that may be present. This screen is of woven wire with 3 or 4 holes per linear inch. The screen following the second washer is similar, but may be 6 or 8-mesh. Too much water must not be used, or satisfactory work is impossible.

The slow-speed 'log-washer' is similar to those used in iron-mining districts, and is adapted for heavier work. One of these machines will handle 1500 cubic yards of material in 10 hours. It is set at a grade of two inches to the foot. The slime flows out at the lower end, where the quantity of fine sand escaping can be regulated by means of the height of discharge and the amount of water used. The coarse sand and gravel are forced up-grade by the revolving paddles to the discharge-end, from which it goes through a double trommel, the inner one having 3-in. holes and the outer one 16 to 20-mesh. Slotted screens are used in these machines, as the material is all granular.

The operation of the log-washer was fully described by W. R. Dodge in the M. & S. P. of March 14, 1914.

The Hydraulic Air-Compressor

By A. E. Chodsko

It is a noteworthy fact that the Pacific coast of the United States, so liberally supplied with natural sources of water-power, already utilized in a number of important hydro-electric installations, should not present a single case of application of a process that has been turned to good advantage by our Canadian neighbors, as also in a few localities in this country and in Europe, namely, the hydraulic compression of air.

The increase of activity in the mining industry, caused by the present upheaval and by the fact that new metallic substances have recently been enhancing the general demand for further development in the opening of mineral deposits, may lend interest to a brief description of a device that some eminent technical writers have been satisfied to pass with the cursory remark that it is "the reverse of the air-lift." Here not improbably lies one reason for the indifference manifested toward hydraulic compression: a common notion exists that the air-lift, while a convenient and widely used contrivance for well-pumping, is unfit for mining practice, and the above opinion, expressed by accepted professional authorities, contributes to relegate in the make-shift class a system that, when rationally used, surpasses in efficiency the most advanced types of mechanical pumping-plants.

Another cause of reticence on the subject may be found in the fact that so far, its successful applications have been made on a large scale, so that the superintendent of a mine of moderate size, and disposing of a limited amount of water, naturally enough deems it useless to look into its possible use for his own requirements. Finally, it is safe to say that while the process itself is by no means novel, little is generally known about its practical use; as in other questions of commercial popularity, both truth and error can be found in these arguments. They are well worth a few moments of attention because not uncommonly have valuable processes or articles been condemned simply because they were applied out of season and under faulty conditions.

In the first place, and without dealing with the air-lift beyond the statement that under ordinary and practicable circumstances it is eminently adapted to mining work, nor is it true that the principle of operation is reversed in hydraulic compression.

True it is that they present some traits of similarity; in both of them, air and water are circulated side by side in immediate contact, and a satisfactory degree of efficiency requires a proper volumetric proportion between the two fluids; in both, also, the principle of operation lies in the difference of weights between two liquid columns in communication. The modes of action of the two machines are, nevertheless, widely different, as also are the determinations of their elements.

J. P. Frizell, who originated that system in 1878, contends that the volume of air drawn by the water into the induction-pipe (Fig. 1) automatically adjusts itself to balancing its contents and those of the return-column. That statement is too vague to satisfy a man who, having at his disposal a given amount of water, wants to know how much air he can raise with it to a given pressure. C. H. Taylor, of Montreal, attempted to answer that question by constructing in 1896 at the Magog mills, Quebec, a hydraulic plant that successfully supplied power to a number of compressed-air motors. In that installation, a volume of free air from 1377 to 1616 cu. ft. per minute was compressed to 52 lb. effective per square inch by a volume of water from 6122 to 7162 cu. ft. per minute respectively, with a fall of from 21.2 to 22.3 feet.

Prof. C. H. McLeod, of McGill University, performed in August 1896 on the Magog plant some tests that showed an efficiency ranging from 53.5 to 62.4%. Encouraging as were these results, they could not outshine customary makes of air-compressors in the competitive field; the tests suggested a better proportion between the main parts of the machine, and further attempts justified that provision.

The efforts of the promoters of the system were rewarded by such marked progress that a hydraulic compressor nowadays can be established under guarantee of showing a higher total efficiency than a reciprocating or centrifugal machine for the same capacity and air-pressure. That efficiency is permanent, because deterioration is practically absent, and no apparent reason exists, barring accident, why a well constructed hydraulic compressor should not be in as good condition after years of continuous use as on the day when water was first turned on. Nor does its relative superiority stop here; while, like any power-plant whatever, the hydraulic compressor demands some attendance, this does not compare with that required by a mechanical plant of like capacity.

This, indeed, does not imply an unrestricted commendation of that type of compressor; its success is primarily subservient to natural conditions that do not exist everywhere, even in regions where it would seem to warrant consideration. But when these requisites are fulfilled, the manager in need of compressed air should be enabled to figure out, at least approximately, as he would for steam, electric, or water power, the nature and the cost of the work involved in the prospective equipment.

Many will hesitate to apply for advice to exclusive firms, who not uncommonly seem to treat a mere request for information as the forerunner of an immediate order,

and they naturally prefer to work the matter out by themselves. Professional inquiries received from mining men satisfied me that the elements of such estimates are lacking, and they have prompted me to present a few pointers that may prove useful. Such suggestions are the outcome of a solution of the problem of hydraulic compression prepared for my personal use, in an effort to co-ordinate the various requirements and physical features of the case. Similar, or perhaps identical, formulae may have been propounded elsewhere; they have not come under my observation.

A strictly analytical treatment of the subject would prove both a useless and a hopeless task: useless because to the man of action, for whom these notes are intended, the sight of a forbidding array of differential equations is a sure incentive to closing the book and dismissing a question presented in that shape; hopeless, because problems of that nature unavoidably involve some purely practical factors, our correct knowledge of which is at best very restricted. If they follow definite laws, these are still, to a large extent, enshrouded with uncertainty, and so long as the requirements do not trespass the limits of present practice, one must rest content for the time being with records of experiment and actual performance as a corrective to the common tendency to generalize unduly the results of limited observations. Such records are unfortunately scarce; too often inquiries of that nature are checked by commercial reticence.

The proposed line of computation assumes only an elementary familiarity with mathematics and physical mechanics; first using it as a checking process, it will be applied to the published results of elaborate tests conducted on a large and successful installation of hydraulic compressors; it next will be used for treating a special case in actual mining practice, the object being to impart an idea of the conditions under which a hydraulic plant deserves competitive comparison with the usual makes of air-compressor.

Again referring to Fig. 1, which indicates the general outline of a hydraulic compressor, air and water will be traced step by step during their passage through the machine, the following notations being used:

- p_0 = atmospheric pressure in pounds per square inch.
- p_1 = absolute highest air-pressure in pounds per square inch.
- Q = volume in cubic feet of free air available for useful purposes.
- c = volume in cubic feet of free air available for effecting compression.
- R = volumetric ratio of the total amount of entrained air to the volume of water.
- S = weight in pounds of one cubic foot of free air at pressure p_0 .
- V_1 = mean velocity in feet per second along induction-pipe.

INDUCTION COLUMN. Water from the fore-bay enters the induction pipe at its top, together with a certain volume of entrained free air, depending upon the velocity of the water. Various devices, which need not be

examined at this time, have been proposed for improving the entraining action of water on the air; it would appear that their main advantage consists in dividing that air into small bubbles, and thus facilitating cooling during compression, but the amount of entrained air is practically the same with or without these devices.

That fact was emphatically asserted by Frizell, and it is confirmed by more recent observation (Peele, 'Compressed Air Plant,' p. 245). At any rate, a mixture of water and of air bubbles is falling along the induction-pipe, the air being gradually compressed as the hydrostatic head increases with the distance below the level of water in the fore-bay. The entire amount of that air, however, is not available for useful purposes, because part of it becomes dissolved in the water.

The latter at saturation contains air to one-twentieth of its volume, irrespective of pressure. The result is that one cubic foot of water entering the induction-pipe contains in dissolution, and with no increase of volume $\frac{1}{20}$ cu. ft. of free air; but as the fall proceeds and that air becomes compressed, its volume diminishes, so that, in order to keep up saturation, the difference between $\frac{1}{20}$ cu. ft. and the actual volume occupied by the partly compressed air must be made up at the expense of the non-dissolved entrained air.

A steady and increasing drain therefore takes place on the initial volume of air, along the induction pipe, until the air and water mixture reaches the lower end of that pipe.

The 0.05 cu. ft. of free air held in dissolution at entrance has now become $0.05 \frac{p_0}{p_1}$ cu. ft. of compressed air at pressure p_1 and the drain on the entrained air, also measured in compressed state, is $0.05 \left[1 - \frac{p_0}{p_1} \right]$ cu. ft., corresponding to $0.05 \frac{p_1}{p_0} \left[1 - \frac{p_0}{p_1} \right] = 0.05 \left[\frac{p_1}{p_0} - 1 \right]$ cu. ft. free air.

In other words, if c cubic feet of water enter the induction-pipe in one second, the total volume of free air moving with it is Rc cu. ft., out of which the water holds in saturation $0.05c$, making the volume of entrained free air at entrance to induction.

$$Rc - 0.05c = c(R - 0.05) \text{ cu. ft. per second.}$$

When the mixture reaches the bottom of the induction-pipe, the drain on the entrained air to maintain saturation is, as above stated, $0.05c \left[\frac{p_1}{p_0} - 1 \right]$ measured in free air, leaving for useful purposes

$$c(R - 0.05) - 0.05c \left[\frac{p_1}{p_0} - 1 \right] \\ = c \left[R - 0.05 \frac{p_1}{p_0} \right] = Q$$

cubic feet of free air per second available for use, and therefore

$$R = \frac{Q}{c} + 0.05 \frac{p_1}{p_0}$$

The limits of available space and of the reader's forbearance would be exceeded by the tedious unfolding of simple calculations that leads to the following results:

Mean weight per cubic foot of mixture of air and water along the induction-pipe:

$$m = \frac{62.4 + 8(R - 0.05)}{2} \left[\frac{1}{1+R} + \frac{1}{1+R} \frac{p_0}{p_1} \right] \text{ lb.}$$

Mean volume of mixture passing per second through induction-pipe:

$$c_1 = \frac{c}{2} \left[1.9 + R \left(1 + \frac{p_0}{p_1} \right) \right] \text{ cubic feet.}$$

V_1 is, in feet per second, the mean net velocity of fall of that mixture, supposed to be constant along the induction pipe.

The corresponding diameter d_1 in feet is given by the relation

$$0.7854 d_1^2 V_1 = c_1 \text{ or } d_1 = 1.128 \sqrt{\frac{c_1}{V_1}}$$

Frizell states that small air-bubbles, say $\frac{1}{8}$ -inch diam.,

induce air by entrainment at the top of the induction-pipe to be 1 foot $= h_1$.

The entrance head, covering contraction is generally reckoned as one-half the velocity-head, or $0.0078(V'_1)^2 = h_2$.

The velocity-head $0.0155 (V'_1)^2 = h_3$.

The friction-head on the length H of the induction is $H \left(\frac{4 V_1^2 + 5 V_1 - 2}{14400} \right) = h_4$.

There is, besides, a loss due to the disruption, in the separation-chamber, of the induction-column moving at the assumed velocity (V'_1) . The corresponding head is $\frac{m c_1}{2g} (V'_1)^2$.

The net work done by the falling water is therefore

$$mc_1 \left[H - (h_1 + h_2 + h_3 + h_4) - \frac{(V'_1)^2}{2g} \right] \text{ ft. lb.}$$

Fig. 1

Fig. 2.

in suspension in still water, have a natural tendency to rise with a velocity of 0.8 ft. per second, varying as the square root of the bubble's diameter. And, therefore, if we assume that the compressed air at the foot of the induction-pipe is in the shape of small bubbles of that size, it will easily be found that the rising velocity at the surface would be $W_0 = 0.8 \left(\frac{p_0}{p_1} \right)^{1/2}$ feet per second, so that, while the net average velocity is V_1 its actual value at the top of the induction must be $(V_1 + W_0) = V'_1$, and as the velocity is supposed constant, this value must prevail along the induction.

The following portions of the total head are lost during the fall: Frizell estimates the necessary head to

RETURN COLUMN. When the mixture issues from the induction-pipe into the separating-chamber, the compression of the entrained air has been completed; the descending column meets a stationary shield that spreads it radially, at right angles with its former direction, and facilitates the separation of the air from the water. The former naturally seeks the upper part of the separating-room, where it enters the air-main. It is obvious that the larger this room is horizontally, the more complete will that segregation be, because the sudden increase of area brings the water to a comparative rest, and it abandons the entrained air-bubbles. The water remains saturated with air, and fills the lower portion of the room, where the submerged entrance to

the return-shaft is placed. The top of it opens in the tail-race, and its vertical depth determines the effective air-pressure.

The size of that ascending passage varies in the few existing installations of that type: it generally is a shaft, vertical or inclined, either enclosing the induction-pipe, or independent of it, but as a rule, of a materially larger cross-section. This, however, is not without exception: Kent (page 623) mentions an installation with a 3-ft. induction and a 4 ft. 9 in. return-pipe, and circumstances are readily conceivable where both may be laid on the inclined surface of the ground. If a is the uniform area of the return-passage in square feet, the mean velocity is $V_2 = \frac{c_2}{a}$ when c_2 is the mean volume in cubic feet per second of the ascending column of air and water.

If the return-passage is a circular pipe of diameter d_2 feet, then

$$V_2 = 1.273 \left(\frac{c_2}{d_2^2} \right)$$

Whatever be the sectional shape of the return-passage, d_2 may be taken as the diameter of an equivalent circular section.

The mean volume c_2 passing per second is

$$c_2 = c \left[1 + 0.025 \left(\frac{p_1}{p_0} - 1 \right) \right] \text{ cu. ft.}$$

The mean weight per cubic foot is

$$m_1 = \frac{62.4 + 0.05 \left(\frac{p_1}{p_0} - 1 \right)}{2} \left[1 + \frac{1}{1 + 0.05 \left(\frac{p_1}{p_0} - 1 \right)} \right] \text{ lb.}$$

The losses occurring during the return flow are represented by

$$a \text{ velocity-head } 0.0155 (V_2 - 0.8)^2 = h_v,$$

$$a \text{ friction-head } \frac{l}{d_2} \left(\frac{4V_2^2 + 5V_2 - 2}{7200} \right) = h_f,$$

when l is the actual length of the return-shaft in feet. The divisor 7200 applies to a rough shaft blasted out of the rock; with a smooth passage, that divisor should be 14,400.

$$A \text{ pressure-head } 2.31 (p_1 - p_0) = h_p.$$

And finally, the work of isothermal compression of Q cu. ft. of free air from p_0 to p_1 is $111 p_0 Q \log. \frac{p_1}{p_0}$ W.

The total resisting work is therefore $[m_1 c_2 (h + h_v + h_f + h_p) + W]$ ft. lb. and equating it to the net work done by the water:

$$m c_1 \left[H - (h_1 + h_2 + h_3 + h_4 + h_5) - \frac{V_1^2}{2g} \right] = m_1 c_2 (h + h_v + h_f + h_p) + W. \quad (1)$$

The efficiency of the process is the ratio of the useful work to the work of falling water, or

$$E = \frac{W}{62.4 c_1 (H - h)} \quad (2)$$

These two expressions furnish all the fundamental data necessary for an installation of hydraulic compression to meet given conditions. The manner of using them will now be exemplified on an existing plant erected in 1906 at the Victoria copper mine, near Rockland, in Ontonagon county, Michigan, the description of which can be found in Peck's 'Compressed Air Plant,'

pp. 242, *et seq.*) and in an article by C. H. Taylor in the MINING AND SCIENTIFIC PRESS of August 18, 1906.

The plan will ultimately comprise three identical units, one of which was in operation when tests were conducted by Prof. F. W. Sperr in May 1906.

Their results, published in the above papers, present slight discrepancies of pressure in connection with the dimensions given in the two descriptions, but that does not affect the result in view, namely, the concordance of the actual data with the above formulæ.

The results of the tests are as follows, in one of three cases:

Atmospheric $p_0 = 14$.

Absolute air-pressure $p_1 = 128$.

Cubic feet free air per second $Q = 198.83$.

Cubic feet water per second $c = 247$.

Diameter of induction $d_1 = 5$ ft.

Working-head $H - h = 70$ ft.

Return-shaft 540 ft. long = l , 10 by 10 ft. (?) with a 2-ft. air-main concreted.

Efficiency $E = 0.8227$.

Assumed temperature $60^\circ \text{ F. } S = 0.0726$.

Applying the previous formulæ, the results are

$R = 1.262$.

$m = 41.273$.

$c_1 = 407.55$ cu. ft.

$m_1 = 53.396$ lb.

$C_2 = 297.28$ cu. ft.

$W = 887,061.75$ ft. lb.

The value of the main velocity V_1 is arbitrary, and lacking a definite law of correlation between that element of the question and the volume of entrained air, one may safely assume that they vary in the same direction, as also do the inertial and frictional resistance, while the size and the cost of the induction-pipe becomes less.

Ivens ('Pumping by Compressed Air,' p. 124) mentions a lift of 840 ft. with a maximum velocity of 22 ft. per second in the eduction-pipe. This has reached 25 ft. in other cases.

In the present instance, a 5-ft. induction-diameter gives

$$V = \frac{c_1}{19,635} = 20.756 \text{ ft.}$$

and assuming the same value, for the sake of comparison, with

$$W_v = 0.8 \left(\frac{p_1}{p_0} \right)^{1/2} = 1.157 \text{ ft. sec.}$$

as the rising velocity at surface, $V_1 = 21.913$ ft., and therefore $h = 1$; $h_2 = 7.443$; $h_3 = 3.721$; $h_4 = 0.025 H$; and $\frac{(V_1)^2}{2g} = 7.113$, making the net work of water $16,820.81 [0.975 H - 19.607]$ ft. lb.

The width of the return-shaft, not given, is assumed equal to its height, namely, 10 ft. Concreting of the 2-ft. air main occupies 3 by 3 ft., = 9 sq. ft., leaving a net area of 91 sq. ft. with an equivalent diameter of 9.52 feet.

The mean velocity in the return-shaft is

$$V = \frac{c_2}{a} = 3.267 \text{ ft.}$$

and therefore $h_5 = 0.0155 (3.267 - 0.8)^2 = 0.092$ ft.

$$h_6 = \frac{540}{9.52} \times \frac{57.027}{7200} = 0.449 \text{ ft.}$$

$$h = \text{as per descriptions} = 272.000 \text{ ft.}$$

$$h + h_5 + h_6 = 272.541 \text{ ft.}$$

Equation (1) becomes

$$16820.81 [0.975 H - 19.607] = 15873.56 \times 272.541 + 887061.75.$$

$$H = 337.99, \text{ say, } 338 \text{ ft.}$$

and subtracting working-head 70 ft.

the pressure-head is 268 ft.

The efficiency is 0.823.

As a matter of fact, the value of H in the Victoria plant is 342 ft., with a pressure-head of 270 ft., a working-head of 72 ft., and an air-pressure of 117 lb., instead of 114 lb. given in the test's records. A shorter length of the total head H was therefore to be expected with the present data, and the above results established the practical conformity of the proposed solution with actual facts.

Another application will now be considered to the case of a mine where the available supply of water is scant, compared with the required amount of air.

The data furnished by the inquirers are

Altitude = 10,000 ft.

Temperature from + 90° to - 25° F.

Minimum flow of water = 500 mi.

Volume of free air required for use = 2000 cu. ft. min.

Effective air-pressure per square inch = 100 lb.

The site makes it desirable to avoid, if possible, the use of heavy machinery and the necessity of important repairs.

An assumed repartition of temperature throughout the year places its mean value, between the mine and sea-level, at 48° F. and this gives

$$p_o = 10.156; p_i = 110.156; Q = 33.33; S = 0.054;$$

$$c = 12.5; \frac{Q}{v} = 2.6664; R = 3.209.$$

A series of calculations entirely similar to those used in the previous example give the following results:

Diameter of induction-pipe, 20 in.

Mean velocity in induction-pipe, 15.47 ft. sec.

Diameter of return-pipe, 28 in.

Mean velocity in return-pipe, 3.64 ft. sec.

Total height, $H = 310.86$ ft.

Working head, $H - h = 79.86$ ft.

Efficiency of the process, $E = 1.863$.

This means an impossibility.

Now, an ordinary air-compressor, operated by a water-wheel, would meet the present requirements, at a total efficiency of 55%, with a working-head of 271 ft. In a general way, it is true to say that theoretically any definite amount of water will perform any definite amount of work under a sufficient head. Nor does the rule suffer exception in the case of hydraulic compression; the recorded impossibility is chargeable, not to the system itself, but to the imposed combination of volume and pressure of the air.

The following results would be found, for the same volume of air and water as assumed in the last example:

Effective air-pressure (lb. per sq. in.).	50	25	8
Total head, H ft.	216.7	148.99	82.38
Working head, $H - h$ ft.	101.2	91.24	63.9
Efficiency	1.098	0.854	0.567

It appears therefore that under given volumetric conditions of air and water, there is a certain pressure corresponding to the maximum efficiency, the upper limit of which is necessarily below unity, on account of the loss incurred from the compression of the saturating air.

In mining, pressures of 100 lb. or thereabouts are generally desired for operating machine-drills. Lower pressures may, however, be useful, for instance, as sometimes suggested, to furnish the first stage of compression for a compound-piston machine; this would permit an ordinary one-stage compressor to perform the finishing stage to 100 lb., a result that could not economically be obtained in a single cylinder.

Another valuable use of low pressures is the operation of serial air-lifts, which only can be mentioned at this place. If, however, an effective pressure of 100 lb. is considered imperative, a hydraulic installation becomes possible by fractioning the plant into several consecutive units acting in parallel so far as air is concerned, and in series for the use of water; in other words, the same water is used several times in succession to produce a cumulative amount of air, the scope of the combination being only limited by the total available fall, controlled, of course, by considerations of economy.

Here are some results of such an arrangement. (Fig. 2.)

Effective air-pressure per sq. in.	100	100
Cubic feet of water per minute.	750	750
Cubic feet of free air per minute at each stage.	1000	800
Number of serial stages.	2	2.5
Total height, H ft.	315.45	304.47
Working head, $H - h$ ft.	84.45	73.48
Efficiency	0.881	0.811

It appears, therefore, that the hydraulic system of compression is adaptable to a variety of forms, under a high efficiency; it is, however, safe to say that its best field of application is characterized by large volumes of air and of water, and that, when their ratio, in the order here named, materially exceeds the unit, a mechanical installation seems, at first glance, more satisfactory.

The problem involves, however, too many conflicting factors to warrant rigid rules of limitation. One unique feature of this type of compressor is that it can be established in a case of emergency when more elaborate machinery would be altogether out of question; and in a remote locality, it may, on that account, prove extremely valuable.

DAMASCUS STEEL, famous throughout the world, owes its peculiarly valuable qualities to the fact that it contains tungsten, according to Duc de Laynes, who published something on the subject in 1844.

The White Caps Mine, Manhattan, Nevada

By John L. Dynan

The White Caps mine is at Manhattan, Nevada, 45 miles north of Tonopah, and has been operated intermittently since 1905. Recent discoveries of good ore on the 300-ft. level have revived interest in this long neglected, although promising, mining district.

Oxidized gold ore was discovered on the surface of the White Caps claims, and an incline-shaft was sunk to a vertical depth of 200 ft. Water-level was at 150 ft., and below that point the ore changed to massive sulphide. The oxidized ore can be readily cyanided, while the sulphide ore is not amenable to direct cyanidation.

In 1912 a party of lessees erected a mill and cyanide plant of 75 tons daily capacity. For a time a good production was made, but when the oxidized ore was exhausted the mine and mill were closed, except for a few shipments, to smelters, of selected high-grade sulphide ore. A process has been designed recently for treating the sulphide ore by roasting and cyaniding, and a roaster

It is to the third type that the White Caps orebodies belong. The ore is a replacement of limestone by quartz, pyrite, arsenopyrite, and stibnite. Calcite, due to recrystallization of the limestone, is abundant. Realgar is common, and cinnabar occurred in small quantities above

FIG. 1. PLAN OF ORE-SHOOTS ON THE 200-FT. LEVEL.

is now being added to the mill. Details of the treatment will be given at some future time, after the mill has been in operation.

The mine is now operated through a vertical two-compartment shaft, sunk in the hanging wall of the orebodies. There are levels at 100, 200, and 300 ft. The total production to date is 19,909 tons of ore, assaying \$19.14 per ton in gold, or \$381,053 gross. This was almost all oxidized ore from above the 200-ft. level.

The sedimentary rocks of the region were originally shale and limestone, which have been intruded by a large mass of granite. The granite outcrops two miles south of Manhattan, also four miles north, and probably underlies the whole district. Later flows of rhyolite cover much of the surface. The sediments have a north-west strike, and dip 55° south west. Metamorphism has been widespread, changing the shale to schist, or quartzite, and altering the limestone to coarse calcite.

The ore deposits occur in the sediments, and are of three types, as follows: (1) Small gold bearing veins, with a gangue consisting principally of quartz and calcite; (2) Low-grade disseminations of free gold through out the cleavage-planes of the schist; and (3) Replacement deposits in the limestone.

FIG. 2. SKETCH-PLAN SHOWING ORE-SHOOTS IN THE LIMESTONE.

the 200-ft. level, but has not been found below it.

An analysis of typical ore is given:

	%		%
SiO ₂	55.8	Sb	0.7
Al ₂ O ₃	1.8	As	1.5
CaO	7.2	MgO	3.2
Fe	8.9	H ₂ O	0.8
S	8.2	CO ₂	9.2

Gold, 1.02 oz. per ton; silver, 0.02 oz. per ton.

This corresponds roughly with the following mineralogical composition:

	%		%
Pyrite	13.8	Calcite	19.6
Arsenopyrite	3.3	Quartz	52.0
Stibnite	1.0	(Ca, Fe, Al) silicates	7.4

Typical ore has much the same appearance as the hard blue limestone of which it is a replacement. Upon close inspection, however, its silicious nature is apparent. The pyrite and arsenopyrite are fine-grained. The characteristic odor of arsenic can be detected upon striking the ore with a pick. Stibnite is found in prismatic and radiating needles and often forms bunches up to four inches in diameter. Samples of ore occasionally assay as high as 8% antimony. Calcite occurs in coarse crystals, and its presence in the limestone is a good in-

dication of the proximity of an ore-shoot. Veins of pure white calcite are frequently followed until they lead to ore.

Realgar is usually found as a thin film coating calcite crystals, or in cracks in the limestone. It also occurs in the shale hanging wall, three or four feet above the ore. Sometimes it forms a film two or three feet square on some smooth surface, and then presents a beautiful appearance. Probably the realgar is a secondary mineral derived from the arsenopyrite.

Cinnabar has been found in small quantities above the 200-ft. level. Its resistance to oxidation made it particularly conspicuous in the oxidized zone.

The condition in which the gold occurs is not known. The sulphide ore, in its raw state, is quite refractory to cyanide treatment, and some of the tests made on it showed identical gold content in heading and tailing

Fig. 3. SECTION THROUGH THE WEST ORE-SHOOT.

samples. The oxidized ore can be cyanided readily, with 90% extraction, and the same is true of the sulphide ore when roasted under special conditions. The gold evidently is in such form that heat or oxidation sets it free. It may be present as a telluride, although no tests sufficiently delicate to determine this have yet been made.

Two principal ore-shoots, known as the East and West, respectively, have been discovered to date. They are separated by a fault, called the White Caps fault, which is older than the ore. A third ore-shoot, less important, occurs along this fault. This is called the shaft orebody, from an old incline, now abandoned, which followed the ore from the surface to the 200-ft. level. The relation of these orebodies to each other, and to the surrounding rocks, is shown in Fig. 1, which is a sketch of conditions on the 200-ft. level.

The limestone in which the ore is found is a hard compact rock of dark-blue color. Its thickness is from 20 to 100 ft. It strikes north-west and dips 55° south-west. The bedding-planes are well defined and average four feet apart. A conspicuous system of joints strikes N 10° E and dips 70° east.

Above this limestone is a thin-bedded shale, called the hanging-wall shale. Below the limestone is the foot-wall

shale, of the same character as the other. Both these shales pass into limestone, becoming more calcareous as they approach it. The exact line of contact is often obscure.

The chief importance of the shales is that they have formed impervious barriers to the solutions which deposited the ore. Calcite veins occur in both the upper and lower shale, but they are small and non-persistent. Numerous faults are exposed. The principal one is the White Caps fault, which strikes west and dips south 60°. On the 200-ft. level, the horizontal displacement is 300 ft. It is marked by a dark-blue gouge from six inches to four feet thick. Faults transverse to the strike of the orebodies are numerous, but they are usually of small displacement. There has also been movement parallel with the bedding of the shale, and both hanging-wall and foot-wall shales contain numerous interbedded layers of gouge, up to six inches thick.

This mine affords an excellent example of the influence of structure upon ore deposition. The ore-bearing solutions have, of course, been confined to the limestone by the impervious shale strata lying above and below it. Within the limestone itself the bedding-planes and joints have a marked effect upon the distribution of the ore. An important ore-shoot will frequently start as a thin seam of calcite along a bedding-plane. Upon driving on this seam, it gradually widens to a calcite vein, from four to five feet wide, and may finally make an orebody as much as 20 ft. wide, with coarse calcite scattered through it. The ore will then stop abruptly against a strong joint or cross-fracture; this joint is frequently filled by another calcite veinlet, and by following this another ore-shoot may be found on some other bedding-plane. Two or three stopes are sometimes superimposed, each ore-shoot following its own bedding-plane, being separated from the others by barren limestone. Fig. 2 is a generalized sketch showing the conditions described above, and Fig. 3 is a section through the West ore-shoot.

There is little doubt that the ore owes its origin to solutions emanating from the intrusive granite. The contact, however, is remote from the orebodies, and contact minerals have not been found in the White Caps mine. Near the contact south of the town, however, coarse calcite and garnet have been found in the sediments, and assays of some of these specimens showed 0.03 oz. gold per ton.

PETROLEUM PRODUCTION in Wyoming at present approximates 31,000 bbl. daily, distributed as follows: Moorcroft field in Cook county, 250 bbl.; Big Muddy, in Converse county, 500 bbl.; Salt creek in Natrona county, 15,000 bbl.; Lost Soldier, in the extreme north-east corner of Sweetwater county, 250 bbl.; Spring Valley, in southern Uinta county near Evanston, 150 bbl.; Pilot Butte, in Fremont county, 100 bbl.; Grass creek, 6000 bbl.; Elk Basin, 4000 bbl.; Gray Bull, 500 bbl.; and Warren, 4000 bbl. The last four fields are all in Big Horn county. The Warren field is just over the line from the Montana boundary.

Cheap Mine Ventilation

Mine ventilation is most important. Metal mines are usually well ventilated throughout the main workings, but distant drifts, raises, and dead-ends generally fail to get sufficient fresh air. In most cases these poorly-ventilated places may get a fair share of fresh air if the circulating air-currents are not cut off or short-circuited. The remedy lies in placing doors at proper places so as to cause the air to pass along to the most remote workings of the mine instead of taking the shortest way out to the surface, as it naturally will if not diverted. When natural ventilation fails, blowers or fans of some description are generally utilized to send the pure air where needed. At some mines the water-blast is used effectively and may be employed at any mine where suitable conditions exist. The essentials are a few inches of water that can be allowed to fall into a vertical box or pipe 10 or 12 in. in diameter, through a height of 30 ft. or more. The water entrains air as it falls and this air is collected in a closed chamber above the water-level and at the foot of the pipe. From here it is conducted by pipes into the mine-workings. An arrangement such as described will send a good volume of air through an 8-in. pipe to a working-face several hundred feet distant. When the water costs nothing the expense of ventilation by this method is merely the cost of the simple equipment at the surface and the pipes leading into the workings.

Where water is not available for use as above described, cheap ventilation may be secured by several other methods; for example, the placing of a wind-sail on a light wooden frame at the surface, so constructed that a current of pure air may be sent into the mine through a pipe by the force of the wind blowing against the sail. The sail should be triangular in shape, 6 ft. broad at the top and 6 ft. long, converging to a funnel-shaped opening at the bottom, which is secured to the top of the pipe. The sail should be so arranged that it can be turned to face the wind. A strong wind directed in this manner will serve effectively to ventilate many hundred feet of mine-workings.

Another device is the stove or furnace, built at the opening to the mine and so arranged that the supply of air must come from the workings through a pipe carried to a point near the face of the drift, or bottom of the shaft. This device exhausts the foul air from the mine, a current of pure air from the outside flowing through the workings to replace the impure air passing out through the pipe. There is no better material for ventilation-pipe than galvanized sheet iron, which, though more expensive in first cost, will not corrode, and therefore is more economical than plain sheet iron. A box-pipe made of lumber will answer the purpose, but it must be made tight its entire length, particular attention being given the joints.

A tightly-covered drain, beneath the floor of the adit or drift, has been successfully employed for ventilation, while serving at the same time as an exit for water. In this case the flow of the stream of water facilitates the

passage of the air. Any miner with a little ingenuity and mechanical skill can make any of these arrangements at little cost of labor and materials, and the result will well repay such expense, as he can then work in a fairly pure atmosphere, and there will be a minimum of lost time in clearing the workings of smoke and gas after blasting.

Tank Construction

Leaching-tanks should be made of clear lumber, red-wood or Oregon pine being best for the purpose. Circular tanks are preferred for permanent plant, though those of square or rectangular section are frequently used. The tank should rest on sills, and, if possible, these should be supported on posts sufficiently high above the ground to admit of easy passage beneath the tank to stop leaks, or to make repairs. Rectangular tanks should be braced with 2 by 6-in. posts mortised into the sills and strengthened with horizontal iron bolts so that the sides may be drawn tight. Upright bolts are also advisable for the same purpose. Tanks of large sectional area are preferable to smaller ones as it is proportionately less expensive to treat a large than a small charge. Ordinarily the rate of leaching is not increased by depth, therefore comparatively shallow tanks are better, leaching being facilitated by greater superficial area rather than by a deeper charge. It is the practice to sluice out tailing when water is abundant, otherwise the tailing must be shoveled out.

False bottoms are usually constructed of slats $1\frac{3}{4}$ in. high and 1 in. wide, spaced 1 in. apart. They are generally screwed to the bottom of the tank, though sometimes the slats are made in two semi-circular segments so constructed that they may be taken up and removed from the tank. The under edge of the slats should be provided with numerous notches which will permit a free passage of solution toward the outlet of the tank. An annular space is also left between the edge of the tank and the false-bottom. The filter of cocoa-matting is laid on the slats, the superficial area of which coincides with the false-bottom, and this is covered with heavy drilling or light canvas (generally 10-oz. duck) cut in circular form and of a diameter 6 in. greater than that of the tank. The edge of the canvas is forced down and the filter secured in place by calking in a piece of $\frac{1}{2}$ in. manila-rope, just long enough to conform to the inside circumference of the tank. The outlet for the solution should be made in the bottom. This opening is covered with a block of wood 3 in. thick and having a hole bored through it at an angle of 30°. Through this hole a rubber hose is drawn; a flange-coupling being used to make a close fit. If tailing is to be sluiced out, a gate 18 to 20 in. wide and 10 in. high should be provided in one side of the tank, the bottom of which is flush with the top of the filter. In tanks of 150 tons capacity, or larger, the discharge-gate is generally placed in the bottom of the tank. In either case care must be taken in construction to prevent leakage.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

ALASKA

The Secretary of the Interior is asking Congress to appropriate \$10,590,672 for next season's work on the railway. Last year \$6,247,620 was voted. Plans were submitted for 240 miles of line to be constructed.

JUNEAU. October returns of the mines on Douglas island were as follows:

	Alaska Mexican	Alaska Treadwell	Alaska United
Stock of broken ore, decrease or increase, tons	-11,237	-16,107	+19,618
Ore crushed, tons	12,635	26,362	48,734
Gold yield	\$14,926	\$56,262	\$66,153
Yield per ton	1.18	2.13	1.35
Operating profit	516	25,320
Construction charge	5,045	16,736	15,003
Loss	4,529	7,704
Other income	3,784	11,521	3,881
Net value of copper plates	32,518	37,567
Total profit	\$52,623

At the Mexican mill amalgamation has been discontinued, and all the gold recovered from concentrate. Treatment of copper plates at the other mills continues.

ARIZONA

GLOBE. The New Dominion Copper Co. is preparing to commence shipping ore mined by lessees. The carbonate ore averages 8%. The shaft is timbered to a depth of 250 ft. Nearly 30 men are employed.

JEROME. Diamond-drilling from the 1400-ft. level of the United Verde Extension may be done to prospect the adjoining Jerome Verde property.

TUCSON. The Tucson Arizona Copper Co. has been organized by J. F. Cowan of Salt Lake City with a capital of 1,000,000 \$1 shares. Auto-trucks are to haul ore to the Sascos smelter at an early date. Sixty men are to be employed for a start.

CALIFORNIA

(Special Correspondence.)—At the Rand mine on Slickrock creek, 8 miles north-east of this place, the south adit has been put in 65 ft. The pay-ore continues for 25 ft., beyond which there is little value. On the north side of the creek an adit was driven 40 ft., showing a little scheelite. A shaft, sunk in the open-cut at the mouth of the south adit shows good ore—7 to 9% WO₃. The ore on the dump is valued at \$50,000. It will be concentrated to 35% for shipment. There is a good prospect of scheelite on the C.O.D. claim on Cedar creek, two miles north of the Rand mine.

Glenville, December 6.

GRASS VALLEY. The Grass Valley Boundary Mines Co., organized by M. J. Brock, is to develop the Oak Tree, New Idea, and Cabin Flat claims under part of the town. About \$10,000 is to be spent.

The Empire mine has 80 stamps crushing ore, and the monthly gold yield is reported to be \$120,000.

OROVILLE. The Federal Government has approved of the new concrete restraining dam across Slate creek, and hydrau-
licdrainking will be started on a large scale at St. Louis and Howland's Flat in the spring.

(Special Correspondence.)—The bonding of the Harvard

mine to W. J. Loring is regarded locally as one of the most important deals that have ever been consummated in Tuolumne county. It is understood that the property, if the examination proves satisfactory to Mr. Loring, will be operated under the same management as the App. Dutch, and Sweeney mines. This transaction, together with the recent acquisition of the Rawhide and other properties by the Silver Peak Mining Co., and the report that the Guggenheims have representatives investigating this field, gives rise to the belief that the county is to benefit considerably. The new flotation plant at the Dutch mine, which was installed by Minerals Separation was given a thorough test this week and proved a success. Its

PART OF TUOLUMNE COUNTY, CALIFORNIA.

capacity is 250 tons daily. Many mining men of the county have inspected the new plant, and as the initial test has given satisfaction, it is likely that flotation will be adopted by other mines.

Additional pumping machinery is to be installed at the Rawhide.

The old adit at the Ocean Star, formerly known as the Duffield, has been repaired, and will be driven 300 ft. in the hope of cutting the lost vein. Over \$250,000 was extracted from the property prior to the time the fault was encountered, a number of years ago. Attempts to find the lost vein have failed so far.

In a statement of the financial affairs of the Nyman Consolidated Mines Co., which recently acquired by purchase the Santa Ysabel mine, it is stated that the Knox and Boyle vein yielded \$3000 during October.

The Deep Channel Mining Co., in which several Los Angeles men are financially interested, will at once commence prospecting operations with a drill on its holdings in the Confidence section.

Sonora, November 30.

COLORADO

CRIPPLE CREEK. The November gold output, as reported by the mills and smelters, was as under.

Golden Cycle	38,000	\$19.00	\$722,000
Portland	11,333	19.85	223,969
Portland	18,700	2.51	45,937
Smelters, Denver and Pueblo	4,550	55.00	250,250
Isabella	2,640	3.00	7,920
Worcester-Rubie	400	3.20	1,280

Total 75,023 \$16.54 \$1,311,356

GEORGETOWN. As treatment tests on dump ore of the Colorado Central Mining Co. have been satisfactory, plans for the

first 100-ton unit are being prepared. A rock-house of 500-ton capacity is to be erected also.

LEADVILLE. Below the 1200-ft. level of the Greenback shaft there is a large flow of water, taxing the pump's capacity to the limit. The cause of this flow is not understood.

The Jamie Lee shaft on Fryer hill, has been drained and the H. S. S. R. & E. Co. is preparing to deepen it. All the mines in this group have been connected to the air-compressor. Zinc carbonate is being extracted from the Tip Top shaft.

IDAHO

ELK CITY. Considerable new work is being done in this district, especially at the Mineral Zone and Black Pine mines. Seattle people have bonded the Mother Lode and other claims for \$25,000.

MULLEN. The Federal M. & S. Co. is to complete enlarging its Mammoth mill early in February; the capacity will then be 2000 tons daily at this and the Morning mill. Except that of the Bunker Hill & Sullivan the Morning mine will have the largest plant in the Coeur d'Alene.

MURRAY. Shortage of water and other troubles have caused a suspension of work at the Golden Chest gold-tungsten mine for the winter. It is probable that a new mill may be erected.

PINE CREEK DISTRICT. The Highland-Surprise company expects to pay dividends at an early date. There is 160,000 tons of zinc-lead ore blocked out. The smelter contract has been revised to advantage. The mill is doing good work in charge of T. Owens. Flotation is part of the process.

MISSOURI

CHADWICK. The old Casey Roberts mine, near here, in Christian county, has been re-opened recently by the Hobart-Lee Tie Co., of Springfield, and shipments of lead ore have been commenced to Joplin. Chadwick is 75 miles east of Joplin and 25 miles south-east of Springfield. This property has been idle since the Civil War, prior to which Christian county was a scene of mining activity, when both lead and zinc ore were mined in large quantity. A man named Gibbs undertook to work the mines many years ago and was found dead in the workings, the physicians said of heart failure, but the miners attributed his death to supernatural causes and refused to work in the mine, since which time nothing has been done until this new company took hold of the property.

JOPLIN. Zinc-ore prices were unchanged last week, though firm. Lead advanced slightly. The Empire District company's electric plant at Riverton had a break-down, resulting in curtailment of ore production. The output of the region was 9208 tons of blende, 446 tons of calamine, and 1390 tons of lead, averaging \$99, \$54, and \$89 per ton, respectively. The total value was \$1,050,845.

MONTANA

BUTTE. The increased price of spelter will make a big difference to Butte & Superior's earnings.

The Bullwacker lessees are to ship 100 tons daily to the Garfield smelter in Utah. November profits were \$11,800.

In the Main Range mine of the Tuolumne lode is 39 ft. wide, assaying 8% copper and 16 oz. silver across 15 ft. and 1% and 6 oz. across the remainder. Boilers and a pump are to be installed.

During the third quarter of 1916 the Davis Daly Copper Co. made a loss of \$2111. The revenue totaled \$107,619. The copper output was 679,098 lb., and silver 57,069 oz. It is said that Butte people are buying shares all the time. About 1/2 of the property is in the zinc area and 1/2 in the copper zone, and future development is expected to reveal considerable ore bodies. High-grade glance and hornite was cut at 2100 ft. last week. This is the lode worked on the 2000 ft. level.

Thirty tons of 90% copper concentrate has been sent to Anaconda by the Butte-Duluth company.

NEVADA

GOLDFIELD. To develop ground adjoining the Goldfield Consolidated and Florence Goldfield, the Red Hill Florence Mining Co. has been organized, being a consolidation of the Red Hill and Florence American companies. No work has been done by the last mentioned for a long time, owing to there being no money for this.

LOVELOCK. At the Lovelock Quicksilver Co.'s mine a 5-ton furnace is producing 10 flasks of mercury each week. The property is at Antelope Springs.

The new mill of the Humboldt County Tungsten Co. at Toulon is yielding one ton of concentrate daily, containing 70% WO₃.

RAND. A report has been made by C. R. Murdoch on the Nevada Rand Mines property, in Mineral county, 15 miles from the railroad station at Rand, or midway between Tonopah and Wonder. The rocks consist of andesite, dacite, and rhyolite; the ore occurs chiefly on the foot-wall and along cross faults. Associated with the gold-silver ore is manganese oxide, characteristic of the district. The ore is oxidized to a depth of 250 ft. The formation is wide, and the pay-ore is confined to a vein from 1 to 3 ft. wide, with lenses up to 8 and 10 ft. A shaft has opened the ground to a depth of 250 ft. Some high-grade shoots have been opened, that between 150 and 250 ft. has been extracted. Some good ore still remains; also a surface dump of 1200 tons of \$15 material. The mine is capable of further development, and is fairly well equipped.

THOMPSON. Ore, coke, and supplies are being taken to the Mason Valley smelter, which is expected to start again early next year.

TONOPAH. Last week the district's output was 9952 tons of ore worth \$195,076.

The old Tybo mine in Nye county has been leased for 20 years to the Louisiana Consolidated Mining Co. of New York. J. B. Farish made a report on the property for Baruch Bros. Hoisting and pumping equipment is to be installed.

VIRGINIA CITY. On December 6 pumps started lowering water to the 2900-ft. level of the Comstock. A review of work done on the lode during 1916 is as follows:

(1) Opening of the Union shaft from the 2000 to the 2700-ft. level, making it the deepest vertical shaft operating in Nevada. This cuts out a long haul of nearly half a mile through the drifts, and in addition greatly helps the ventilation. (2) Opening of the Union and Sierra Nevada winze from the 2500 to the 2700-ft. levels and the additional discovery that it is in good condition to 2900 ft. (3) The purchase and installation of pumps in the Mexican-Ophir winze, which have now commenced work, and will drain the North End mines to the 2900-ft. level, opening ground that has been flooded for over 30 years. (4) A great improvement in ventilation which has made work at every point underground easier and cheaper. (5) The discovery of ore in Union, which has placed that mine in better financial condition than for 36 years. (6) The repairing of the Ophir shaft, the up-cast shaft of the North End mines, thereby protecting them from any interruption of ventilation, and the enlarging of drifts that carry the air in many places. And (7) the commencement of work at the Combination shaft, which means active mining in the middle group, the centre of the Comstock lode.

OKLAHOMA

CARBON. The mill that was moved from Reeds, Missouri, to the U. S. Mining & Smelting Co.'s mine here, has been finished, with a capacity of 300 tons daily. Coal is used for fuel. The ore is all of high grade, and occurs in flint formation at a depth of 200 feet.

MIAMI. The largest operator here is the Commerce Mining & Royalty Co. A 150-ton mill is at work on its Turkey Flat, and one of 250 tons' capacity on the Blue Goose. A 300-ton

plant is being erected near that on the latter. In storage the company has about 4000 tons of zinc-blende for sale.

Another large producer is the Miami Zinc & Lead Co., which has two mills, one of 250 tons, the other of 300-ton capacity. The largest pump in the Missouri-Kansas-Oklahoma region is being worked. It is a 16-in. Prescott make, pumping 2500 to 3000 g.p.m. from a depth of 380 ft., draining the entire Commerce field.

NEW MEXICO

MOGOLLON. An initial dividend of 1% has been paid by the Oaks Company. Similar monthly distributions are to continue.

The Mogollon Mines Co. treated 4000 tons of ore in November.

HURRO MOUNTAIN COPPER CO.'S MILL AT TYBONE, NEW MEXICO.

SANTA RITA. Among the dividend-payers of December, the Chino Copper Co. will distribute \$2.50 per share.

OREGON

RIDDLE. The Eldorado Copper Mining Co., capitalized for 2,000,000 shares at \$1 each, has been organized by Spokane and Oregon men to take over and operate the Banfield copper mine, 32 miles east of this place, on the main line of the Southern Pacific railway. The reported price is \$300,000, part cash and the remainder shares in the new company. The incorporators are Andrew Laidlaw and S. W. Miller, of Spokane, and others. The Banfield mine is one of the best known copper properties in Southern Oregon, and many well posted mining men regard it as the largest high-grade copper deposit in the State.

SOUTH DAKOTA

The statistical branch of the U. S. Geological Survey has issued its report of mineral production for South Dakota and Wyoming in 1915. It shows that in 1915 there were 33 mines operating in the Black Hills, in South Dakota, producing 1,889,975 tons of ore, having a value of \$7,406,305 in gold and \$101,331 in silver. The production of lead was only 3107 lb., worth \$146. This output shows an increase of \$76,439 over the production of 1914.

In the Black Hills, the Homestake was the principal producer, as it always has been. The total production of gold in the Black Hills from the discovery of the placers in 1875 to the end of 1915 has been \$192,693,945, and of silver \$4,315,005, a total of \$197,008,950. The production of placer gold in the Hills, which in the early years of the country—from 1876 to 1880 amounted to millions of dollars—in 1915 was but \$1589.

Wyoming, in 1915, mined 4216 tons of ore, which produced gold valued at \$14,592, silver \$426, and copper 447,246 lb., worth \$78,268, a total of \$93,286, which was an increase of \$85,899 over the output of 1914.

LEAD. The Homestake Mining Co. has posted the following notice: "The Homestake Mining Co. will pay to all employees whose names appear on the December 1916 pay-roll, additional wages amounting to 7% of the year's salary for 1916. Checks for same will be given out on the January pay-days."

UTAH

FAUST. Fifty miles north-west of this place, which is on the Salt Lake Route, is the Dugway district, which is said to be fairly active. A number of properties are giving gratifying results, some shipping ore. The ores contain lead and copper.

PARK CITY. On December 30 the Silver King Consolidated pays 15c. a share, equal to \$95,250. This makes a total of \$285,750 for 1916. The daily output is 50 tons of \$45 to \$65 ore; a recent shipment netted \$63. Ore comes mostly from a depth of 1500 and 1650 feet.

On January 1 the Silver King Coalition pays 15c. a share, or \$187,500. This makes \$750,000 in 1916. The weekly output of crude ore and concentrate is over 500 tons.

The Judge Mining & Smelting Co. pays 25c. per share on the 20th. This is equal to \$120,000, and makes \$435,000 for 1916.

SALT LAKE CITY. Affairs of the Ohio Copper Co. are still unsettled, and Utah shareholders are watching the decision of the U. S. District Court in the matter of the title being given to the Stockholders' Protective Committee, whose representatives in New York offered a check for \$1,350,000 to liquidate the bonded indebtedness.

Later advice: The Court has decided to allow of a reorganization of the Ohio Copper Co. Shareholders have subscribed for over \$500,000. The new company is to have 2,500,000 \$1 shares, \$50,000 to be held by the treasury.

During the 9 months ended October 1, 1916, the Utah Metal & Tunnel Co. and Bingham-New Haven Co. made a profit of \$567,737. The gross value of the gold-silver-lead-copper ore was \$1,262,752. The weight of ore and concentrate was 60,364 tons. Water sold realized \$37,162. Mining cost \$2.42, and milling \$1.01 per ton. On August 15 a dividend absorbed \$342,473. Development covered 10,190 ft., at \$10.45 per foot. Results were encouraging. The flotation plant started in October to treat tailing and low-grade copper-iron ore. Another crusher and ball-mill will add to the daily capacity 75 tons, making a total of 300 tons. The copper and lead has been sold for delivery during the first half of 1917. The bonded debt was reduced \$145,500, leaving \$229,500 outstanding.

TINTIC. November production of the Tintic district was 44,200 tons, valued at \$1,100,000. Last week was the heaviest for any period in 1916, namely, 13,000 tons. For 11 months the total is estimated at 416,100 tons, valued at \$10,000,000.

To open ore being mined at 1800 ft. depth, the Chief Consolidated contemplates putting in pumps and sinking. One of the difficulties in this district is the height that water must be pumped in order to get it to the surface.

From December 1, Tintic mine-owners are to pay miners and others 25c. per day extra. Miners will get \$3.75, machinemen \$4, shaft-men \$4.50, and shovelers \$3.50 per shift.

The Colorado company is sinking its shaft from 1500 to 2000 ft. Walter Fitch is the contractor.

The May Day's upper levels are yielding 75-oz. silver ore.

WASHINGTON

CHEWELAH. On January 15 the United Copper Co. distributes 1c. a share, or \$10,000. A shaft is to be sunk from the 1000-ft. level, where the ore-shoot is 1300 ft. long and 8 ft. wide. A. McDonald is now superintendent.

NORTHPORT. During the four months ended October 31 the Electric Point mine shipped 151 carloads of ore. The carbonate ore averaged 22.89%, and the sulphide 71.47% lead. Receipts were \$90,602, not including settlements on 43 carloads. This is a new mine, discovered a year ago.

REPUBLIC. There are 150 men employed in this district, and the daily ore production is 200 tons. Results at the Northport S. & R., Last Chance, Knob Hill, and others are reported as good.

SPOKANE. The Loon Lake-Blue Bird Copper Mining Co., capitalized for 1,500,000 shares at 25c. each, of which 500,000 shares are to be held in the treasury, has been incorporated by Andrew Laidlaw, H. H. Schallenger, Lester P. Edge, Joseph McCarthy, and M. L. Moe, all of Spokane, to take over and develop the Blue Bird and Dupont claims, adjoining the Loon Lake Copper Co.'s holdings, 45 miles north of Spokane.

VALEY. There is considerable activity among the recently-discovered magnesite deposits near here.

CANADA

BRITISH COLUMBIA

TRAIL. The electrolytic copper refinery at the smelter is to be enlarged 50%. In the last week of November the smelter received 11,215 tons of ore.

ONTARIO

CORALT. Silver production of the Nipissing for 10 months totals \$2,228,658. Shipments, including custom bullion, were \$3,172,582.

PORCUPINE. In a few weeks the aerial tram being constructed across Pearl lake from the McIntyre company's Extension mine to its mill will be finished, enabling the plant to treat 600 tons daily.

SENBURY. On account of the large increase in nickel mining and proposed new plants, this district is short of electric power, fully 20,000 horse-power.

MEXICO

HIDALGO

PACHUCA. During October the Santa Gertrudis company's profit was only \$1700, from 14,823 tons. Owing to shortage of supplies, it was found impossible to operate the mill at more than half its normal capacity.

SONORA

ALAMOS. Development continues at the Plata-Fina company's property 8 miles east of here. Eight shafts have been sunk from 90 to 115 ft. deep. This, and other work totals 2000 ft., all by windlass. The owner, T. P. Brinegar of Tucson, Arizona, has continued work practically through the years of revolution. Some high-grade silver ore is being opened in a new shaft. Only one other American concern has worked here during the trouble, but two Mexican mine-owners have kept working with arrastras. The other Americans quit 10 months ago, and now none are working within 60 miles of Alamos.

The COLUMBIA Section of the A. I. M. E. met at Spokane on November 25. Stanley A. Easton of the Bunker Hill & Sullivan presiding. The membership has grown from 129 to 158. W. H. Linney was elected chairman, Oscar Lachmund vice-chairman, and L. K. Armstrong secretary-treasurer. C. G. Warfel, assistant professor of mining in the State College at Pullman, read a paper on electric reduction of iron ores of eastern Washington. D. F. Haley of the Interstate Callahan company, and others discussed flotation problems.

The John Fritz medal was awarded in January 1916 to Dr. Elihu Thomson for achievements in electrical inventions, electrical engineering, industrial development, and scientific research. The medal will be presented to him at a meeting to be held in Boston on December 8, 1916.

The Mackay School of Mines, University of Nevada, Reno, will begin its short course for prospectors on January 5, thence to February 2. No charges are made, save a fee of \$5 to cover cost of supplies. During the previous two courses the attendance was 21 and 29 students.

The Utah Section of the A. I. M. E. met at Salt Lake City on December 16. J. M. Callow presented a paper on the "Notes on Flotation, 1916," and Erwin Wille, "Manufacture and Use of Sulphuric Acid."

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

BERNARD MACDONALD is at New York.
H. L. HUSTON has gone to Ely, Nevada.
G. V. MICHELL has gone from London to Tomsk, Siberia.
ROBERT E. CRANSTON has gone to Colorado and New York.
NELSON DICKERMAN returned here from Bolivia on December 4.

H. B. LOWDEN, of the Colorado Iron Works, is in San Francisco.

T. W. MATHER is leaving Guayaquil, Ecuador, for Pacific Grove, California.

A. J. SALE, assayer at Battle Mountain, Nevada, is spending the holidays at Los Angeles.

W. W. MEIN and WALTER KARRI-DAVIES left San Francisco for New-York on December 4.

J. H. MACKENZIE made a visit of inspection to Atolia, in San Bernardino county, last week.

W. E. THORNE, engineer to the Lenskole Gold Mining Co., Lena region, Siberia, is in London.

GEORGE B. HOLDEBER has recently been appointed superintendent to the Northern Pyrites Co., at Northpines, Ontario.

CHARLES E. VAN BARNEVELD has been appointed supervising mining engineer and metallurgist to the U. S. Bureau of Mines.

DRUMMOND MACGAVIN, who is with the Canadian Mining Corporation, at Toronto, is spending the holidays in San Francisco.

M. E. MACDONALD was here early this week, from Los Angeles, accompanied by his brother, JOSEPH MACDONALD, of Guanajuato.

RALPH H. MOORE and F. L. STACK, formerly with the Morococha Mining Co., Morococha, Peru, returned to Mexico early in December.

FREDERICK W. GAY announces that he has opened offices as consulting engineer in power, etc., for mines, at 310 Sansome street, San Francisco.

W. J. ELMENDORF has joined G. M. WELLS and DONALD G. CAMPBELL in a new firm to be known as Campbell, Wells & Elmhendorf, with offices at Seattle.

HENRY F. COLLINS has resigned the executive management of the Huvelva Copper & Sulphur Mines and has accepted the position of consulting engineer to the company.

JAMES MACNAUGHTON, general manager of the Calumet & Hecla, is now living in Boston, where he will spend most of his time, making occasional visits to Houghton.

D. P. THOMAS has resigned as superintendent for the Moose Mountain, Ltd., at Sellwood, Ontario, to accept the management of the Davidson Mines, at South Porcupine.

C. T. GRISWOLD, of the Associated Geological Engineers, has transferred his activities from Wyoming to Oklahoma. M. L. FETTER, managing engineer of the engineering division of this firm, visited New York recently.

H. J. WALLACE, formerly field engineer for the Anaconda company at Great Falls, has been appointed superintendent of construction in place of F. J. BRUE, who has resigned to accept the position of chief engineer for the British America Nickel Co. under E. P. MATTHEWSON.

AUGUSTUS D. COX has resigned as superintendent of the Union Hill mine at Grass Valley to become manager of the mining ventures being financed by the G. S. Johnson Co. ERIC MACBRYEN, who was formerly general manager of the Union Hill mine, will now assume the resident management of this and the other mines that have been acquired by the new corporation known as the Gold Point Consolidated Mines.

THE METAL MARKET

METAL PRICES

San Francisco, December 12.

Antimony, cents per pound	14
Electrolytic copper, cents per pound	35
Pig lead, cents per pound	7.75-8.75
Platinum, soft and hard metal, per ounce	95-105
Quicksilver, per flask of 75 lb.	\$80
Spelter, cents per pound	13
Tin, cents per pound	45
Zinc-dust, cents per pound	20

ORE PRICES

San Francisco, December 12.

Antimony, 50% metal, per unit	\$1.00
Chrome, 40% and over, f.o.b. cars California, per ton	15.00
Magnesite, crude, per ton	6.50-9.00
Manganese, 50% (under 35% metal not desired)	16.00
Tungsten, 60% WO ₃ , per unit	17.50-20.00

New York, December 6.

Antimony ore is unchanged and quiet at about \$1.50 per unit. Molybdenite: A little business has been done at \$1.75 per pound.

Tungsten: Several hundred tons has changed hands in the week at \$18, and an advance is looked for.

EASTERN METAL MARKET

(By wire from New York.)

December 12.—Copper is quieter and irregular; lead is scarce and irregular; spelter is quiet but steadier.

COPPER

Prices of electrolytic in New York, in cents per pound.

Copper production of 26 large mines in North and South America totals 1,700,000 lb. for 10 months, a great increase over this period in 1915.

Anaconda produced 25,500,000 lb. in November, a decrease of 6,000,000 lb. due to cold weather. Inspiration yielded 10,600,000 lb., Old Dominion, 3,650,000 lb.; Miami, 4,968,500 lb.; East Butte, 1,648,040 lb.; Chile Copper, 4,098,000 lb.; Cerro de Pasco, 5,700,000 lb.; Arizona Copper, 4,380,000 pounds.

Dividends declared are: Champion, \$6.40; Shattuck-Arizona, \$1.25; United Verde, \$1.50 (\$4,050,000 for 1916, of which W. A. Clark receives \$4,000,000); Old Dominion, \$3.50; Utah Copper, \$3.50; Nevada Con., \$1.50; Ray Con., \$1; Chino, \$2.50 per share.

SILVER

The silver market is strong. Slight recessions in price are the natural reactions of a healthy market. The present strength is due to firmness of China exchanges, apart from the European and Indian currency demand. There is a shortage of sycee

(bars) in the East. As long as Chinese export business keeps active there is expected to be a firmness of exchange.

On December 8 silver valued at \$1,056,000 (say 1,400,000 oz.) was shipped from San Francisco to Shanghai.

Tin is quiet at 43 cents.

ANTIMONY

Importers are maintaining their quotations firmly, and report a fair business, but dealers say that business is dull. The quotation for Asiatic grades is 14 to 15.00c, duty paid, New York.

ALUMINUM

The market is firm, but unchanged, at 63 to 65c. for No. 1 virgin metal, 98 to 99% pure.

Eastern Metal Market

New York, December 6.

The quieter tendency in copper has continued, largely because near-by metal is scarce, even first quarter being difficult to obtain, but the strength of prices is unimpaired. It is believed, however, that they have reached their apex.

Statements pertaining to possible over-production of zinc have disturbed the trade. Second-hands have been selling this week and have caused prices to soften.

Lead is stronger and quotations are more uniform following an announcement by the A. S. & R. Co., December 5, fixing its New York price at 7.50 cents.

Tin has been dull and lower, the November statistics having been interpreted unfavorably.

Antimony and aluminum are unchanged.

In pig iron there is a quieter market, but quotations are firm around \$29 to \$30, furnace, for eastern Pennsylvania and Buffalo iron, also at central-western furnaces.

The November production of pig iron dropped below the enormous production of October. The total was 3,311,811 tons, or 110,394 tons per day, against 3,508,849 tons in October, or 113,189 tons daily. Even at the lessened production no other month than October equalled the November output. The production always drops in November for seasonable reasons, while this year the furnaces had to cope with shortages in their coke deliveries, and the virtual breaking-down of furnaces that had been hard pressed for months. Several were blown-out for re-lining. The export demand for pig iron is extending more and more to foundry grades, although the demand for steel-making iron continues heavy.

COPPER

November was a great month in the copper market, the volume of sales being estimated at around 600,000,000 lb. Next to September, the month just closed was the largest in the history of the copper industry. In the past week buying has been much quieter, although there still is unsatisfied demand. The absorption of the metal has been so great that first-quarter delivery is about as difficult to arrange as it is to procure spot. The scarcity of near-by copper has served to restrict sales, while another influence making for a quieter market is that the larger consumers have covered their needs. Although there is less doing, prices are as strong as ever, even a trifle stronger. Both electrolytic and Lake for delivery to the end of the year is held at 31.50c., while first quarter is about 31 to 31.50c., second at 32.50 to 33c., third 30.50 to 31c., and fourth 30 to 30.50c. Strictly spot metal commands 35c., and small lots have sold over this figure. It is the general opinion that prices have reached the top notch, and considerable satisfaction is felt thereat, for the reason that further advances would be dangerous, according to the trade. A saving clause in the situation is that the bulk of the buying of late has been done to cover contracts actually in the hands of consumers, and only the abrogation of these contracts would make the buyers decline to take the copper purchased. Of course, contracts are not supposed to be broken, but most of the war contracts have cancellation clauses. The London market for spot electrolytic yesterday was strong at £170, or £1 higher than a week ago. November exports totaled 21,433 tons. In 11 months of this year exports totaled 229,659 tons, against 233,918 tons in the same period of 1915, an increase of 65,741 tons. It is regarded as certain that the large French inquiry which came before the trade a few weeks ago will soon develop into business. In the past few days dealers have handled the bulk of the sales.

ZINC

On Monday of this week (December 1) the upward trend of

prices was halted by a decision on the part of second-hands that it was time for them to take profits. The New York price has reached 13.25c., but under the pressure of offerings it dropped, until yesterday, the 5th, to 12.75c., New York, and 12.50c., St. Louis, for prompt, were done. First quarter was about 1c. per lb. less. The selling at concessions was started entirely by dealers, but it was not long before some of the large producers were meeting the lower prices. Certain large producers, however, are not at all dismayed by the break in the market. They point out that there has been a steady rise, lasting through all November, and that perhaps a little check just now may be healthy, particularly in view of the fact that it probably will bring down the price of ore. They are of the opinion—in fact, one or two little bets have been made on the subject—that the price will touch 14c. early in January. They hold this view despite the expressed opinion of some experts with regard to over-production, views which were in part responsible for the decision of dealers to sell. It is undoubtedly true, as C. E. Siebenthal of the U. S. Geological Survey pointed out early in the year, that production has increased enormously, yet the consumption is great also. Exports in November totaled 16,098 tons. Production will be cut down this winter, as it is every cold season. Snows interfere with mining and the cold hampers the gas supply and furnace operation. From Joplin comes the news this week that two out of three large steam turbines used by an electric-power company supplying the district had broken down under the strain of overload, and would be out of commission for two or three weeks, the one turbine operating being used to pump-out the mines. This news quickly had the effect of checking a decline in the price of ore. The London spot market was 10s. lower yesterday at £58 10s., as compared with a week previous. Fundamentally the position of the metal is strong, despite its ups and downs because of the influences referred to. Sheet zinc is unchanged at 21c., f.o.b. smelter, carload lots, 8% off for cash.

LEAD

The A. S. & R. Co. finally took action yesterday; and in the course of the day advanced its price twice. It first announced that its New York quotation had been advanced from 7 to 7.25c., then, that it had fixed the New York price at 7.50c. The independents already had been quoting over 7.50c., New York, for prompt delivery, in fact some were asking 7.75c., New York. December lead has been at a premium because of its scarcity, little or none being available at any price. Following the action of the big producer the market steadied at 7.50 to 7.62½c., New York, independents asking 7.40c., at St. Louis. Prior to the announcement of the leading producer it was difficult accurately to gauge the market, inasmuch as prices covered a wide range. The London spot quotations continue unchanged at £30 10s. Exports in November totaled 1436 tons. Lower prices for lead are not looked for in the near future.

TIN

Since the last report the market has been dull. On December 4 some likely-looking inquiry came out, but it was followed immediately by the announcement of the November statistics. These did not look good to consumers and they withdrew from the market. The most adverse feature of the figures was the showing that the total visible supply had increased 3771 tons in November. The total visible supply October 31 stood at 17,415, whereas a month later it amounted to 21,186 tons. Deliveries into consumption in November were fair, amounting to 3165 tons, of which 365 tons arrived at Pacific ports. Total deliveries in 11 months of the year totaled 51,553 tons against 41,962 tons in the same period of 1915, an increase of 6591 tons. The quantity now afloat is 6168 tons.

RECENT PATENTS

1,199,818. CONVEYER SYSTEM. Staunton B. Peck, Philadelphia, Pa., assignor to Link-Belt Company, Chicago, Ill., a Corporation of Illinois. Filed Jan. 16, 1915. Serial No. 2521.

1. A conveyer comprising successive groups of over-lapping parallel conveyer sections and means for independently driving each group.

1,196,049. PROCESS FOR REMOVING IRON FROM TIN ORES. Günzel von Rauschenplat, Steglitz, Germany, assignor to Barilla Limited, London, England, a Corporation of Great Britain. Filed Jan. 28, 1914. Serial No. 815,029.

1. The herein described process for removing iron from iron-bearing tin ores, which consists in subjecting the ore to a reducing treatment at a temperature at which the tin will remain in a form insoluble in acids, while the iron contents will be reduced to a form readily soluble in acids, and then subjecting the resulting product to treatment with acid.

1,196,699. ART OF PRODUCING TUNGSTEN POWDER. Frederick G. Keyes and Robert B. Brownlee, Hoboken, N. J., assignors to Cooper Hewitt Electric Company, Hoboken, N. J., a Corporation of New Jersey. Filed Feb. 17, 1915. Serial No. 8769.

The combination with a crucible, of fused sodium tungstate within the same, a porous cup dipping into the fused material and permitting the said material to enter the said cup to substantially the level of the material in the crucible, an anode extending into the crucible and the fused material therein and a cathode dipping into the material within the porous cup.

1,199,794. MINE-CAR. Warren V. Johnson, Bloomsburg, Pa., assignor to American Car and Foundry Company, St. Louis, Mo., a Corporation of New Jersey. Filed Aug. 4, 1916. Serial No. 113,127.

1. In combination in a mine car, a wood floor portion, metallic body bands extending beneath said floor near its ends and intermediate its ends and secured directly to said floor, corrugated metal side body sheets secured directly to said body bands, flanged members connecting the side body sheets with said floor, longitudinally spaced journal boxes connected to each of said flanged members by bolts extending through said journal boxes, the floor and said flanged members, a fixed end wall and a hinged gate.

1,199,962. SINTERING-MACHINE. Sophus P. C. Borson, Salida, Colo. Filed Aug. 23, 1915. Serial No. 46,959.

1. In a machine for sintering and roasting ore, the combination with a movably supported ore carrier comprising an impervious bed member with projecting joint members, of a fixed ore retainer comprising two oppositely disposed perforated side walls provided with depending flanges adapted to combine with the said joint members to form sliding joints, means attached to the said ore retainer for forcing a blast of air through the material under treatment, means for supporting the said ore carrier and ore retainer, and operating means attached to the said ore carrier adapted to produce comparatively slow forward motion and a comparatively rapid return motion thereof, substantially as shown and described.

1,197,843. APPARATUS FOR SEPARATING OILED CONCENTRATES FROM THE GANGUE OF ORES. Ralph T. Mishler, Pomona, Cal. Filed Sept. 13, 1915. Serial No. 50,457.

1. In an apparatus for separating concentrate from the gangue of ores, the combination with a longitudinal pulp receiving case, provided with transverse partitions separating the interior of said case into pulp receiving chambers, and

with superposed pulp separating receptacle supported by said case and provided with passages from the respective pulp separating chambers, of pulp conducting stand pipes for conducting the pulp from one pulp receiving chamber to a superposed pulp separating receptacle, and having their lower ends connected with the inlet passages from the pulp receiving chambers, said chambers being provided with separate outlet passages leading from said pulp separating receptacles to said pulp receiving chambers, a longitudinal shaft extending through said case and said chambers, and means on said shaft within said chambers for forcibly discharging the pulp from said chambers through said stand pipes above the level of the pulp in the pulp separating receptacles.

1,201,151. ORE-CONCENTRATOR. George T. Cooley, Joplin, Mo., assignor to one-half to James Athel Brent, San Francisco, Cal. Filed Nov. 10, 1914. Serial No. 871,307.

1. In an ore concentrator, the combination with a frame, of a bolster, means for suspending the latter from the frame, a plurality of tables pivotally and yieldably connected with the bolster at one end, means connected with the tables for adjusting their inclination, and a head motion attached to the bolster.

2. In an ore concentrator, the combination with a frame, of a plurality of three-point suspension tables suspended in the frame, one of which suspensions is a horizontal pivot, and means at the sides for adjusting the inclination of the tables simultaneously upon said pivots.

1,197,137. METHOD OF REDUCING METALS. Robert J. McNil, Perth Amboy, N. J., assignor to The Roessler & Hasslacher Chemical Co., New York, N. Y., a Corporation of New York. Filed Jan. 2, 1913. Serial No. 739,710.

1. A method of reducing metallic compounds to their metals by electrolysis consisting in raising the boiling point of said metals by pressure on the molten electrolyte while maintaining the temperature of the electrolyte below its boiling point at atmospheric pressure.

2. A method of reducing metallic compounds to their metals by electrolysis consisting in raising the boiling point of said metals by pressure of a compressed gas on the molten electrolyte while maintaining the temperature of the electrolyte below its boiling point at atmospheric pressure.

1,197,331. PROCESS FOR THE MANUFACTURE OF SULFURIC ACID. Lucien Paul Basset, Paris, France. Filed July 5, 1916. Serial No. 107,597.

1. A process of producing sulfuric acid which comprises passing gases containing sulfur dioxide and oxygen in contact with a catalytic substance capable of partially oxidizing the sulfur dioxide, removing the so oxidized portion, and thereafter absorbing the unconverted residue of sulfur dioxide in a calcareous material suitable for use in making cement.

1,197,199. APPARATUS FOR ROASTING AND SINTERING ORES. James Gayley, New York, N. Y., assignor to American Ore Reclamation Company, New York, N. Y., a Corporation of New York. Filed May 6, 1916. Serial No. 95,775.

1. In a continuous sintering machine of the kind described, the combination with a wind box, a series of grate bearing pallets, and supports therefor which permit the pallets to be moved over the continuous top of the wind box, of series of sectional seal bars or curtains intermediate to the pallets and wind box adapted by their adjustment to automatically close the joints between said pallets and the wind box and thus prevent impairment of the air-tight union between the two.

1,198,882. TREATING LEAD MATTE. Utley Wedge, Ardmore, Pa. Filed Jan. 29, 1913. Serial No. 744,894.

The mode herein described of roasting lead matte in a furnace of the superposed hearth type, said mode consisting in carrying said lead matte forwardly through the furnace, retarding sulfur elimination by abstracting heat from the furnace until the sulfur has been so far reduced as to permit of the free application of the heat necessary to effect the desired desulfurization, and then applying such higher heat.

Company Reports

Consolidated Gold Fields of South Africa

An abstract of the report of this great company for the year ended June 30, 1916, should interest American mining men on account of the company's interests in this country. The principal holdings throughout the world are in 34 companies—gold, tin, potash, power, etc.

The realized profit—mainly from dividends received on investments, after deducting debenture interest, etc., was £440,141. After paying dividends and taxes the balance was £283,917; and after allowing for depreciation, and adding the previous balance, there remains £231,740 (\$1,120,000). From this was paid 7½% on ordinary shares, amounting to £150,000.

Some details of the properties controlled by the Consolidated Gold Fields company are as follows:

MINES IN THE TRANSVAAL

Name	Reserves, tons	Ore treated, tons	Yield per ton	Cost per ton
Simmer & Jack.....	1,935,000	788,700	\$5.26	\$3.50
Robinson Deep.....	1,849,000	646,900	6.84	4.60
Knights Deep.....	2,614,000	1,307,300	3.64	2.90
Simmer Deep.....	1,492,000	762,800	4.12	3.85
Jupiter.....	1,178,000	234,000	5.04	4.62
Sub Nigel.....	214,000	93,260	9.56	7.52
Crown Mines.....	9,938,000	2,332,000	6.18	4.32
Government (Mollderfontein).....	4,368,000	627,200	6.42	4.86

In the last two the company has a minor interest. The total working profit from the other companies was \$424,000, a small reduction compared with the previous year, although more ore was treated. Owing to the War the companies lost a large number of efficient employees, and had to pay increased charges on supplies, bullion, and taxes.

TRANSCONTINENTAL CONSOLIDATED OIL CO. The area held in the Panuco and Huasteca fields of eastern Mexico totals over 10,000 acres. Six wells are yielding 10,000 bbl. daily. Equipment is equal to three times this quantity. The properties produced 736,881 bbl. Profits earned were sufficient to pay dividends on preferred stock. The International Petroleum Co. produced 582,124 bbl., which was handled by the Transcontinental company.

GRANVILLE MINING CO. The Canadian Klondyke Mining Co. recovered 72,464 oz. of gold in the last season, and 34,112 oz. to September of the current season. As there was a shortage of repair parts the dredges did not operate at highest capacity. The North West Corporation removed 779,000 cu. yd. of overburden.

SIERRA PACIFIC ELECTRIC CO. Net earnings of this concern in 1915 were \$279,710, and in seven months ended July 31, 1916, \$173,376, a slight improvement. Subsidiaries serve 25% of the total population of Nevada.

YUBA CONSOLIDATED GOLD FIELDS. During the year ended February 29, 1916, the dredges recovered 2,133,529, equal to 12.02c. per yard. Expenses totaled 4.27c. per yard. In the five months to July 31, 1916, the average grade was 12.87c., with 3.7c. cost. The present rate of profit is \$1,800,000 per annum.

NATOMAS COMPANY OF CALIFORNIA. The net profit in 1915 was \$1,570,799. For the seven months ended July 31 the net result was \$588,789, a low return due to less dredging operations.

LA GRANGE MINING CO. About 2,000,000 cu. yd. was sluiced last season, costing 4c. per yard. The total clean-up was \$39,763, and expenses \$80,000, making a loss of about \$40,000.

If a tunnel is driven 1100 ft., so as to shorten the sluice by a half, thus decreasing its maintenance, and increasing the grade, about 4,000,000 cu. yd. could be handled at 1½ to 2c. per yard. It is not possible to sample the gravel ahead of hydraulicking.

MISSISSIPPI RIVER POWER CO. This company's great power-plant is at Keokuk on the Mississippi, half-way between Chicago and Kansas City, and 140 miles north of St. Louis. The possibilities for sale of power in this region are enormous. In 1915 gross earnings were \$1,651,269, and net \$1,326,868. For seven months in 1916 the profit was \$792,227.

AMERICAN TRONA CORPORATION. Considerable annoying litigation was settled in April, when the Supreme Court of California decided in favor of the company involving holdings of shares in the California Trona Co., which owns claims on Searles lake. Other suits by claim-jumpers were awarded the corporation. The last question in dispute is the settlement with the United States government on the validity of the California Trona Co.'s claims at Searles lake. After many tests a process was evolved for treating the brine. Concentrated salts are being produced at Trona at the rate of 50 tons daily, from 400,000 gal. of brine. This quantity of potash is to be increased by adding to the plant. A refinery is well on toward completion at San Pedro, near Los Angeles. The Trona salts have a high market value, and a contract has been closed for 3500 tons to be shipped by the end of 1916. The Trona railroad of 30 miles, connecting Trona with the Southern Pacific at Searles, had a revenue of \$53,000 and \$23,000 profit. Mining in the vicinity is responsible for these good results.

Prices of Chemicals and Old Metals

Acetic acid, cents per pound.....	50—55
Arsenic, white, cents per pound.....	6—6½
Barytes, prime white foreign, per ton.....	\$35—40
Borax crystals, cents per pound.....	7½—7½
Caustic soda, 76%, cents per pound.....	3½—4
Creosote, cents per pound.....	2½—3
Cresol, per gallon.....	\$1.36
China clay, imported, per ton.....	\$18—30
Feldspar, per ton.....	\$8—10
Fuller's earth, foreign, powdered, per ton.....	\$25
Hydrochloric acid, commercial, cents per pound....	1½—1½
Lead acetate, white crystals, cents per pound.....	13½—14
Litharge, cents per pound.....	9½—9½
Nitric acid, cents per pound.....	4½—6½
Potassium cyanide, cents per pound.....	70—72
Phosphate rock, Florida, 68%, per ton.....	\$2.75—3.00
Potassium iodide, cents per pound.....	4
Pyrite, furnace size, imported, cents per unit.....	15½
Silver nitrate, cents per ounce.....	42½
Soda ash, cents per pound.....	3
Sodium nitrate, cents per pound.....	3
Sulphur, crude, per ton.....	\$35
Sulphuric acid, 66° B., per ton.....	\$20—21
Talc, American white, per ton.....	\$9—12
Tar oil, cents per gallon.....	35—40
Aluminum, old cast, cents per pound.....	32—32½
Copper, light, crucible, wire, or heavy, cents.....	21½—25½
Brass, cents per pound.....	14½—17
Lead, cents per pound.....	6½—6½
Tin, block, cents per pound.....	40
Zinc, cents per pound.....	9—9½
Electrotype, cents per pound.....	6½
Old rails, per ton.....	\$25
Old car-wheels, per ton.....	\$24
Heavy cast-iron scrap, per ton.....	\$17
Machine-shop turnings, per ton.....	\$10

Recent Publications

SAFETY AND EFFICIENCY IN MINES. By Edwin Higgins. Bulletin No. 3 of Industrial Accident Commission of California. P. 14.

NOTES ON THE INVENTION, DEVELOPMENT, AND INTRODUCTION OF THE FLOTATION PROCESS. By A. Stanley Elmore. P. 20. Reprint from the MINING AND SCIENTIFIC PRESS, and issued by the Ore Concentration Co. of London.

A SERIES OF TREATISES ON THE RARE METALS. By Herman Fleck. P. 73.

These lectures were delivered at meetings of the Colorado Scientific Society, Denver, in 1915 and 1916. The metals discussed were tungsten, molybdenum, vanadium, and uranium. We have already abstracted from the notes. At this time the publication is worth securing.

U. S. Bureau of Mines, Washington, D. C., 1916:
ORE-SAMPLING CONDITIONS IN THE WEST. By T. R. Woodbridge. Technical Paper 86. P. 96. Ill. index.

Important points from this useful investigation were abstracted for the Press of November 11.

MELTING ALUMINUM CHIPS. By H. W. Gillett and G. M. James. Bulletin 108; Mineral Technology 14. P. 88. Index.

U. S. Geological Survey, Washington, D. C., 1916:
MEASUREMENT OF SILT-LADEN STREAMS. By R. C. Pierce. Water-Supply Paper 400-C. P. 13.

GEOLOGY OF THE HOUND CREEK DISTRICT OF THE GREAT FALLS COAL FIELD, CASCADE COUNTY, MONTANA. By V. H. Barnett. Bulletin 641-H. P. 17. Map.

THE GOLD LOG MINE, TALLADEGA COUNTY, ALABAMA. By Edson S. Bastin. Bulletin 640-I. P. 3.

THE YUKON-KOYUKUK REGION, ALASKA. By H. M. Eakin. Bulletin 631. P. 88. Ill., maps, index.

Notes on a district that has no deposits of value, as far as discovered.

Book Review

LUBRICATING ENGINEERS' HANDBOOK. By J. R. Battle. P. 323. Ill., plans, index. J. B. Lippincott Co. Philadelphia, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, \$4.

We have perused this work on a very important subject with much interest, and consider it worth a place in every oil and mechanical engineer's library. To the mining man, the statement that "the most essential and yet the most neglected detail necessary to obtain the best results from pneumatic tools (drills, etc.) is proper and efficient lubrication," will be found appropos; also the remarks on lubrication of pumps and cars. In these times of high-speed engines, whether steam or oil-driven, lubrication is of paramount importance. Engines are not the only machinery to be considered, there being a thousand and one machines that require oil or grease at some part. Wherever two surfaces work against one another, friction and heat results, requiring a lubricant to reduce this as low as possible. The author terms this a "friction tax." Picking out several chapters of the book we find tersely given and practically illustrated, the theory of lubrication, petroleum and other lubricants and their manufacture, vegetal oils (under the caption "vegetable oils"), tests of oils and grease, miscellaneous notes on oil, steam engines and turbines, bearings, lubricating apparatus, air-compressors, automobiles, Diesel engines, internal-combustion engines, locomotives, and the cost of lubrication. The index of 20 pages is well arranged.

Industrial Notes

Information supplied by the manufacturers.

Catalogue No. 14 of the NATIONAL TANK & PIPE CO., Portland, Oregon, consists of 48 pages of well-illustrated data, including four full-page colored views of pipe-lines installed by the firm. Brief discussions are given on the strength, life, capacity, and uses of wood-pipe. Ten reasons are stated for using this product. Fittings for pipe are shown and described. As far back as 1799, New York used wood-pipe for its water-supply. Some useful tables are appended.

The INGERSOLL-RAND CO. of New York has issued form 8311 of 16 pages on 'Little David' pneumatic riveting-hammers, inside trigger pattern. These hammers are offered in six sizes, the dimensions and specifications of which are listed in the catalogue. An important feature of this tool is the rivet-set retainer designed to meet the regulations and requirements of the safety appliance laws enacted in the various States. Form 3130 of 24 pages is on class ER-1 power-driven single-stage straight-line air-compressors. Machines are built in various sizes from 6 to 12-in. stroke, with a piston displacement capacity of 52 to 955 cu. ft. per minute and are equipped with the Ingersoll-Rogier type of air-valve.

Several types of tractors are in use for hauling ore, supplies, and machinery in mining districts. A machine has been devised by R. Hamilton of Geyserville, California, and severe tests are said to have proved its reliability. It is 3½ ft. wide and 7 ft. long, and weighs 1750 lb. The motor, gearing, and frame are of good design. Distillate is used for fuel. The special advantage, as may be seen from the picture, is the traction arrangement. The periphery of each wheel is fitted with 16 two-pronged forks, 7 in. long and 9 in. wide, which dig into the ground, giving great tractive effect, especially on rough or muddy roads. The clearance of the frame above ground is 10 in. under normal working conditions. Like several other tractors this one was developed on a farm.

The suit brought by the KOERING CYANIDING PROCESS CO. against the Wasatch Utah Mining Co., of Sandy, Utah, has been decided in favor of the Koering company. The evidence presented showed that the Koering company installed a unit for the treatment of what was represented as being a large ore-body, but which subsequently proved to be not the case, as after a three weeks' run the ore supply was exhausted. The Wasatch company will return the equipment and also pay damages to the Koering company for misrepresentation of the facts in the case. The Koering company has issued a pamphlet entitled, 'The highest development of the copper-leaching art,' in which is described the use of its plant for sulphuric acid instead of cyanide. Detailed costs are given.

Announcement has been made by the WESTINGHOUSE ELECTRIC & MFG. CO. of an extension of its present bonus system to include salaried and office employees on hourly rates, by which they will receive a bonus of 8% of their salary each month, providing their total excusable time absent and late during the month does not exceed 6 hours incurred on not over three occasions. An additional 4% will be given each month to the employee who has not lost any time from work during the month through absence or tardiness, thus enabling those affected to obtain an increase in earnings of 12% for a 100% attendance. Several thousand employees in the Pittsburgh district are benefited by the granting of the bonus. The company has issued a circular discussing electric-furnace equipment. One great improvement is the automatic regulation of current, the Thury regulator being extensively used.

EDITORIAL

T. A. RICKARD, Editor

SUBSCRIPTION of \$5,000,000 to the purchase of United Kingdom 5% notes by the copper companies under Jackling management is announced at New York. This is stated to be "a matter of reciprocity," seeing that the Allies are buying so much of the copper produced by this group of mines.

AMONG the destructive consequences of the War we should take note of the loss of metal as cargo on ships that are sunk as well as the metal in piping and fittings that are sent to the bottom, where none of it can be salvaged. On the *Chemung*, sunk on November 27, was a large tonnage of copper, zinc, and steel.

IT IS estimated that the increase in the sum of wages distributed in the organized industries of the United States since the beginning of 1916 is about a billion dollars. Notwithstanding this colossal increase in wages it is doubtful whether the average worker has gained any advantage, for the increase of income is less than the rise in the cost of living.

SELECTIVE flotation, based on the Owen idea, has been developed at the Broken Hill South mill to the point of obtaining a 62.6% lead concentrate containing 45.6 ounces of silver and only 9.6% of zinc. The silver minerals escape water-concentration owing to their fissibility, causing them to break into minute flakey particles, which are well adapted to being buoyed by bubbles.

OUR friends at Oatman make a mistake in comparing their rich and prosperous little district with the Rand, or with the Mother Lode, as we note is done by Mr. C. F. Spilman, who has taken charge of the publicity department of the Oatman Bureau of Mines. The Rand goldfield is mined continuously for a length of 40 miles and produces over \$180,000,000 per annum. The Mother Lode is worked along a length of 100 miles and produces \$6,500,000 per annum. Oatman is good enough; no benefit can come from comparisons that are essentially exaggerations.

THE Western Federation of Miners has changed its name to the International Union of Mine, Mill, and Smelter Workers. Some change was urgently needed, but the substitution of a new name will not suffice. We would like to see the organization out of the hands of men that have used labor-unionism to terrorize industry and to promote anarchy. The "international" suggestion is not good. All of us—employers and employees—

are subject to the laws of our State and Nation, and to them we owe respect. Labor troubles cannot be settled on an international basis. If the idea is to incite international strikes, it is wrong.

PEACE has greater terrors than War for Wall Street, as was evident last week. The near panic that came between the German proposal and the Russian rejection of negotiations is an indicator of what may happen when a genuine approach is made to cessation of fighting. The episode proves that New York is far from being the financial centre of the world—it is the biggest gambling centre, that is evident.

LARGE bonuses are being paid by mining and manufacturing companies to their employees at Christmas or New Year. This shows the right spirit, for abnormal profits are being made; but it is to be hoped—against experience—that the abnormality of the times and the exceptional character of the bonuses will be appreciated, so that the reversion to ordinary wages will not be accompanied by unreasoned bitterness between employer and employee.

QUEER shifts may be made to prolong the life of a mine. We remember one that appeared, after careful examination, to have enough ore to last for two years, yet operations continued for five years. Long afterward the engineer that had made the examination met the superintendent and asked him how he managed to do it. Did the mine pay during the extra three years? "No," he replied, "it did not, but the boarding-house did—and I ran the boarding-house."

AMONG the sensible and kind actions to be associated with this Christmas we note the club-house for railroad men to be built by Mr. J. Parke Channing at a little junction point, in the iron region of northern Michigan, that is named after the donor. Our contemporary the *Mining Gazette* mentions the matter in a friendly way and expresses the hope that other men similarly successful in the Copper Country will follow the example and show some practical remembrance of the locality where they started on the road to fortune.

GOOD WORK in flotation is being done at the Atlas mine, near Sneffels, Colorado, where a silver-lead ore assaying 21% lead and 8½ oz. silver per ton is being treated at a recovery of 90% of the lead and 93% of the silver. By re-treatment of the flotation product, on tables, the silica content is reduced from 15-20% to

about 10%. The recovery is 25% better than it was formerly when using ordinary wet concentration. The concentrate assays 16% lead, 35 oz. silver, and 0.22 oz. gold. The cost of milling, treating only 100 tons daily, and concentrating 10:1, is 94 cents, to which 12 cents per ton must be added for royalty.

ON another page we record the conclusion of the Shockley episode. It will be seen that the directors of the American Institute realize that a mistake was made and regret the apparently mandatory tone of the message sent by them to San Francisco. It was the friendly letter of the President, however, that had most to do with the prompt acceptance of the apology and the expression of goodwill that was voted by our local section. The incident, and the discussion of it, has been salutary. Having regard to sundry criticisms—always welcome—from some of our friends on the Eastern seaboard, we take the opportunity of stating that it is part of the proper function of a professional journal to protest against any trespass on the rights of a member of the profession and to defend him when occasion arises.

NECESSITY is proverbially the mother of invention. This is illustrated by two of the photographs accompanying Mr. Sumner S. Smith's article on the Caehe Creek dredge. One photograph shows how a small single-cylinder gasoline-engine, mounted on a truck, is geared to a sprocket that, in turn, is geared to the wheels of the truck, which hauls the ore, and thereby displaces a much less effective mule. This locomotive brings ore two miles from the Cymru mine to the dock on Moira Sound, on the east coast of Prince of Wales island. The other illustration is not as clear because the engine is covered by canvas. A small gasoline-engine is belted to a bull-wheel operating a piston that drives a cross-cut saw held in place by the two guides, which can be seen clearly. The log is held in place by a couple of 'dogs.' The pond fills with wood that has been sawed; the machine is then pulled ashore, and an abundant supply of fuel is left on the beach when the tide recedes.

OWING to the lavish production of copper ore at this time, most of the larger smelters are unable to accept small lots of custom ore for treatment. This works a hardship on the owners of little mines that can supply a limited tonnage of relatively high-grade ore. There are many small mines that can produce a considerable tonnage of 5 to 10% ore, such as would yield a satisfactory profit at the present price of the metal, if the ore could be smelted. The big smelters are overloaded with ore sent to them under contract from regular customers, including mines controlled by the smelting company itself, so that they find it inexpedient to accept ore from the small shipper, except on terms so exacting as to pile insult on the injury that the minor producer already feels, owing to being denied an opportunity to share in the benefit of an abnormally high market for copper. We appreciate the bitterness of his position and advise

him to investigate wet methods of extraction. Undoubtedly the smelter congestion should stimulate experimentation in the hydro-metallurgy of copper.

RUSSIAN gold production has varied during the past 12 years between \$22,000,000 and \$35,000,000 per annum, the last four years showing a gain of about \$2,000,000 successively. The latest available figures are \$26,750,000 for 1914. The correctness of these Russian gold statistics are open to doubt, as the exact amount of gold recovered is not really known, partly because the department dealing with the industry is not as well organized as our own or those of other countries, and partly because of the legalized theft prevailing in the gold mines, causing a good deal of the product to be smuggled across the border into China, which for many years was credited with a preposterous production of gold. However, the somewhat stationary condition of gold mining in Russia and Siberia, it is reported, has at last attracted the serious attention of the Government, which is showing an inclination to act upon the resolutions passed at the various conferences that have been held in the empire, including the gold and platinum producers, calling for measures of support and stimulation. The area allotted for exploitation of gold has decreased in recent years, also the quantity of gravel treated, for, at present, most of the Russian yield is from placers. Gold is known to exist, in quantity inviting mining, over a million square versts, of which only 5000 versts is being exploited. The Government is being urged to throw open more of the Crown lands for mining exploration, to send geological expeditions into the field, and to facilitate colonization of the known gold-bearing areas. Lack of the means of transport hinders new work even in regions that are open to exploitation. Good roads are wanted, as also the extension of the postal and telegraphic services, which are the nerves of industry. It is said that many old dumps of half-washed gravel, left by operators using crude methods, are available for profitable re-treatment. Lode mining for gold is yet in its beginning, and in this respect affords a curious contrast with the recent growth of activity in copper, lead, and zinc mining, particularly in the Ural, Akmolinsk, and Altai regions. Of course, the War and its financial exigencies should cause the Russian government to do all it can to stimulate the winning of gold from the ground. We believe that it will, and in doing so that it may find it advisable to draw further on American experience.

BY courtesy of the Secretary of the Colorado Scientific Society, we have received the report of a committee of that society on the revision of the mining law, covering the ballot taken on the questions submitted by the Mining and Metallurgical Society of America, as related in our issue of November 11. A majority of the committee was unwilling to waive the requirement of 'discovery' before location, preferring that possession of a claim be legalized pending a *bona-fide* effort to find ore in place. It

was decided, however, that even if location be permitted prior to 'discovery,' patent should not issue until this requirement, of discovery, has been fulfilled. The committee was divided on the question of one discovery sufficing for more than one of a group of contiguous claims, but it agreed that every claim should be separately marked by monuments. Likewise a unanimous vote was given for placing no limit on the number of claims any person or association may locate. No support was accorded the proposal to compel the recording of claims in the U. S. Land Office, but the suggestion was made that the time for recording with the County Recorder be shortened to 60 days. The suggestion to substitute money payment in lieu of assessment work was not endorsed, nor was the Committee in favor of crediting excess assessment work from one year to the next, but urged that adequate provision be made for ensuring *bona-fide* performance of assessment work, to be valued at the rate of wages current in the particular district. On the main question, the Committee approved the proposal to abolish the extra-lateral right. Not only did it vote against recording in the Land Office, but it approved the suggestion of an appeal from the decisions of the Land Office to a court of competent jurisdiction. These are the main findings and we give them because they represent current opinion among mining engineers in a great mineral region. In the main, they are likely to reflect the views not only of engineers but of many owners and operators of mines. However, they throw no light on the opinion of the prospector and of other humble but extremely useful members of the mining public. Any change in the law is not likely to be made, nor should it be made, without considering the effect of it on the varied interests to be affected thereby; nor should any fresh enactment be passed without weighing carefully the confusion inevitably to arise from the conflict between the new and the old regulations. The old law, defective as it may be, has been filtered through the courts until its intent is clear. Any new law will be difficult to interpret until it also has gone through a protracted baptism of litigation.

The Great Calamity

The end of another calendar year and the coming of the season of goodwill finds civilization in the midst of a murderous conflict that shows no prospect of an end. The early appeal to our sympathy for the victims of ruthless aggression and the instinctive lift given to our imagination when we realized the splendor of sacrifice that was driving thousands into the jaws of death have alike lost their force. The iteration has dulled sensibility. Are we not becoming callous? and is not that callousness more horrible than the horrors of the battlefield? One can read in the daily paper that at Chicago wheat was down yesterday "under the depressing influence of peace talk," and one can hear people on the train or tram say that they are "sick of the War," as they turn a page to read about the latest football match

or the newest scandal in suburban life. Is not that picture more sad than an abandoned trench in which the dead lie five yards apart; is it not more brutalizing than the bomb that falls from a Zeppelin? We think it is. How many of our more intelligent readers have begun to look upon the War as an unnecessary and wasteful quarrel, as other people's quarrels usually seem to those that go about their daily work in normal tranquillity of mind. To such of us as are interested in mining has not the War become the barometer of metal prices and is there not a danger that the cessation of the organized calamity on the other side of the Atlantic will mean to us not a consummation devoutly to be wished but a check to abnormally favorable markets? We have not even salved our consciences with giving money to help the distressed; what we have done is too small to assuage self-contempt. We hear a lot about Belgian relief; out of \$227,500,000 devoted to that purpose, the people of this country have subscribed \$10,000,000—and we eat \$200,000,000 worth of candy annually! A few heroic souls have gone to fight or to drive ambulances, and even these are condemned for their un-neutrality. There has been a lot of petty collecting of money, much of which is typified by the four young women that hunched in aid of a Belgian fund: they subscribed \$1 apiece, but the luncheon cost \$31.50. People must lunch, dine, or dance, they must be amused by song or play, before they will give a dollar—and when they have given a pittance they turn complacently from the untold sorrows of the great nations from which all of them originated. Let the Red Indian ignore the Great War—or the Negro—but not a nation that consists of European immigrants and their descendants. Whether a man's forefathers landed on Plymouth Rock or on Ellis Island, he has some tie with some country in Europe, and he must have a pitiful imagination and a stunted spirit if he cannot give a heart-throb for those, on whichever side they may be, that are risking all that they have and hope in the valley of the shadow of death. Must neutrals be ignorant? must they cease to think and to imagine, while going on their way in a fierce scramble to get all the 'prosperity' that is being created by the misery of the other half of the world? Must we accept the dictum of our wretched morning paper when it says that "as neutrals, we are not concerned to know the merits or demerits of either side"? Surely not; as rational beings we cannot help being keenly interested in the events that are the greatest in human history. This thing at which we look from day to day is no Yaqui uprising in Sonora, it is not a Villa raid on our border, exciting as that may seem to the hysterical reporter; this drama on which we look is the most tremendous episode in the history of the race; it is a privilege to be alive to see it and it is a crime to treat it as if it were a cinema show for children. We are spectators of the greatest calamity that has befallen civilization: the very cradle of what we call modern civilization is being smashed to smithereens, and the peoples that were deemed the most civilized are cutting each other's throats by tens of thousands. We cannot stop it—we

have not the organized force to do so; we cannot call a halt—we have not the moral authority to do that; we can do nothing—for we are neutral; but we can at least be alive to the fatefulness of the conflict and of the part that it must play in the destiny of the world and in that of America. Already the fateful contest has served to disclose the diversity of the elements out of which this nation has been made. The War has been a disintegrating force south of the Great Lakes as it has been an integrating factor north of the boundary. The participant has been warmed to a great loyalty; the spectator has been chilled to a cold misgiving. The temperature of this melting-pot of alien races has been kept so low, by official request, that it is only a mixing-pot, in which the ingredients tend to become mutually repellent. To complete the fusion of the unlike elements—the scrap and the dross as well as the ore and the flux—that have been shipped across the Atlantic to be melted in the crucible of generous democracy, we must have the warmth of a wide charity, the heat of a great ideal, and the fire of self-sacrifice. The cold glare of prosperity will melt nothing; it will only illumine the inequalities of existence and the unfairness of the scramble for wealth. We need the glow of generous sentiment. Let us bow our heads in sorrow for the countless thousands that have seen their homes smashed like a child's toy by the engines of destruction; for the horde of miserable ones whose weary tramp across the devastated fields could almost be heard by us if the more insistent roar of guns did not drown the tread of their tired feet; for the millions of prisoners herded like cattle in barbed-wire enclosures. What is Christmas to these? What is it to the homes bereaved by the loss of husband or son? What is it to the fatherless children and the widowed women that sit beside the dying embers of a winter evening? What is Christmas to the Belgian enslaved by the invader, to the Pole or Rumanian whose hearthstone lies buried amid smoldering ruins; what is it to the Serbian or Montenegrin whose country has been trodden underfoot, or to the wretched Greek who has become the shuttlecock of opposing policies? What is Christmas, what is civilization, what is life to the million Armenians that have been the victims of an organized scheme of brutality and bestiality? We are proud, if we are not patriotic; can we imagine the degradation of spirit that these tragedies bespeak? Think of these; think of the shame of the conquered and the pain of the dispossessed; think of the travail of spirit, the unutterable misery, and the blank despair that is the Christmas portion of millions of fellow-men not far from us; and thinking thus, let us condemn the gluttony of wealth that is making New York a byword; despise the commercialism in Chicago that regrets the whisper of peace; and disclaim the gaiety in San Francisco that ignores a world of sorrow, famine, and murder. If we cannot fight, if we do not give, let us at least on Christmas day pause for one moment and bow our heads in bitter humiliation of spirit that we can do so little to lessen the pain and the suffering that man is causing to man.

Belgian Kiddies

Two days after the foregoing editorial was written we received the circular letter headed 'Belgian Kiddies, Ltd.,' which we publish on another page. It is signed by 60 members of the mining-engineering profession and if time had permitted it would have been signed by 6000 more. We ask our readers to give it their thoughtful consideration and then act forthwith. Is it not true that many of us have soothed our self-respect by admiring the splendid work done by Mr. Hoover and his associates, most of them mining engineers, in Belgium; have we realized sufficiently that the principal gift of America to Belgium has been neither money nor food, but a priceless executive ability in which as engineers we can take pride, of course, because it has been contributed by a distinguished member of our own profession? The circular letter suggests how great has been that gift to Belgium from America but how miserably small has been the financial aid given to the Relief Commission. Is it not time to correct the pitiful discrepancy? Should not our natural pride in the work of the Hoover commission take a more substantial form? Let us then shake the Chairman by the hand and in the act transfer something golden from our hand to his. There is no need to eulogize the great performance of Mr. Hoover—it has become a part of current history; it were better to express our admiration in tangible form. It is not necessary to pour praise on the equally unselfish labors of his associates, but we would like to say that the university founded by Leland Stanford has shown a spirit that places it among the great institutions of human culture—a university indeed. The group of men recruited so largely from California has done a big thing and it is high time for the mining profession to recognize it. The opportunity to do so is given to us now by this appeal in behalf of the Belgian children. 'Belgian Kiddies, Ltd.,' it is called, as if to suggest the prospectus of an undertaking in which big dividends are assured; as assuredly they are—the gratitude of thousands of little ones that can be saved from the sickness threatened by lack of food. The preferred stock now issued in this glorious enterprise is offered at \$12 per share; it is expected to sell 10,000 shares and so to raise \$120,000. With this money it will be possible to provide one meal per day for 10,000 children during the coming year. As the prospectus says, each share sold means 365 square meals for one child. The corporation is organized under the Laws of Humanity and the legality of the issue is guaranteed by the Court of Last Resort. If you subscribe you will have the satisfaction of knowing that the money will be used with maximum efficiency, for the overhead expenses of the Commission for Relief in Belgium are only $\frac{3}{4}$ of 1% of the gross cost. We have no hesitation in urging our readers to respond promptly to this appeal for the little ones that are the pitifully innocent victims of the great calamity. Send your remittances to Belgian Kiddies, Ltd., at 120 Broadway, New York.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Belgian Kiddies, Ltd.

The Editor:

Sir—An informal committee of mining engineers, from all over the United States, is undertaking to give our friend Herbert C. Hoover a Christmas present, by taking off his shoulders part of the burden which he and his associates have been carrying for the last two years and a half.

During this time, the United States has received a great deal of gratitude from Belgian people which it has not deserved. To the Commission for Relief in Belgium all praise is due for its work. The C. R. B.—as it is known—has distributed in Belgium goods costing about \$227,000,000, of which the United States has contributed \$10,000,000, or about 4.3% of the total; and much of this has come from a few large foundations. The commission has purchased in the United States goods to the amount of \$125,000,000. We have not even paid a fair commission thereon. Reduced to a per-capita basis, we have given 8 cents apiece. Canada has given 18 cents per capita, New Zealand \$2.34 and little Tasmania \$6.25 a head. Yet the United States gets most of the credit. We have been obtaining gratitude under false pretenses.

This is naturally discouraging to us who know and appreciate the work of American engineers in Belgium. These men have been keeping alive a population of nine million on one meal a day. This is not enough for children. (Would you like it yourself?) At present one million children are failing in health, and the C. R. B. has asked us Americans to assume the proper feeding of these children as our little share of the big job.

To do this right the C. R. B. has started to give the children a nourishing noon-day meal, and it has not the money to carry it on. This costs only one dollar per month per child (three cents a day). This seems incredible but as the overhead expenses of the C. R. B. are only $\frac{1}{3}$ of 1% of the gross cost you will understand that this is real engineering efficiency.

As engineers we want to show our appreciation and so we have organized an informal syndicate to float a new venture. We would like to cable Hoover before Christmas that we will take a block of "Belgian Kiddies" off his hands. Don't you want to come in with us?

Pan-Americanism—A Myth

The Editor:

Sir—I have found your recent editorial (November 18, 1916) under the above heading of especial interest, having myself had experience in South America. With parts of the article I thoroughly agree; some of the arguments set forth, however, seem erroneous, at least merely theoretical. For example, why should an extension of our trade in one direction, south, necessarily result in curtailment in another, east? If commercial intercourse with Europe remains profitable after the War, it will continue. Many of the tropical agricultural products of South America are needed and used in this country. Europe has, in the past, supplied most of the manufactured articles consumed south of Panama, but cannot we, as a nation, with intelligent preparation, make the things needed by South Americans and make them the way they want them in competition with Europe?

I admit the existence of racial, political, legal, social, religious, and educational differences existing between the United States and the South American countries, but has our brother from northern Europe any advantage over us in these respects? Would we be any more of a hermit nation if we broadly took into account all differences, made allowances therefor, and proceeded to overcome any difficulties that might threaten therefrom? The question is, can we, after the War, compete with Europe in South American commerce? If so, we now have an opportunity to take our share of this trade. This question can only be answered finally by the business man who is willing to back up his practical knowledge, confidence, and fearlessness with the investment of his capital.

If we have been hypnotized by a figure of speech let us drop it; but why limit our trade if found profitable in

other directions than the east. Above all let our citizens have protection at home and abroad, let us have our own merchant marine and let us have an adequate navy to guard our coasts and our shipping.

Los Angeles, December 8.

Electric Heater for Solutions

The Editor:

Sir—A simple and effective electric heater can be made for heating solutions or pulp in a tank from material that may be found around any mine or mill repair-shop.

In running a cyanide test recently it was desired to heat the solutions in an experimental tank that was so situated that no method of heating was available but to use electricity. An endeavor was made to purchase something that would do the work, but nothing could be found locally that was satisfactory, nor could the dealers suggest a heater that would do. After a few trials of

the $\frac{1}{4}$ -in. pipe or a substitute, tying it securely and winding any high-resistance wire around it in a spiral so that the windings do not run together. A convenient way of doing this is to use a lathe with a thread-feed.

This heater was attached to the ordinary lighting-circuit with an extension-cord and could be removed at will. On a 120-volt circuit the current consumed was from 6 to 8 amperes. The pulp reached a temperature of 100° F. in about 8 hours. It is set inside the tank and the heat adjusted by merely turning on or off the current as required. No dimensions are given as each case would involve different conditions.

F. DEAN BRADLEY.

Reno, Nevada, December 4.

Effects of Faults on Richness of Ore

The Editor:

Sir—In several different mines operated under my own direction, and in others as well, I have noticed that,

ELECTRIC HEATER FOR MILL SOLUTIONS.

various inventions, the heater shown in the accompanying sketch was evolved.

The container was an experimental tank of the pachuca type 48 in. high by 20 in. diameter with the customary column in the centre so as to permit nothing of broad dimensions to be used. It was necessary to have the heater of greater proportions longitudinally than transversely.

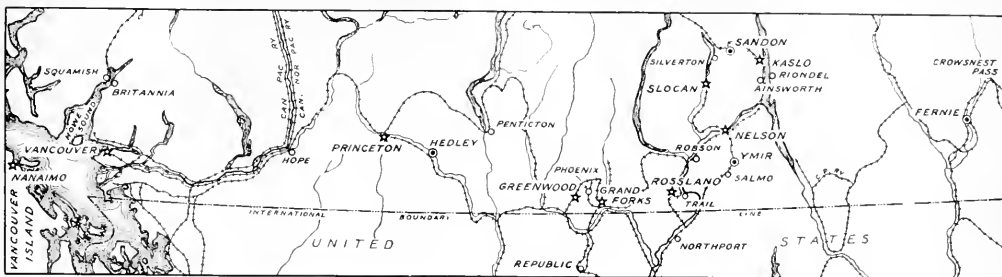

Three resistance-coils from dismantled arc-lamps were secured from the power company's scrap pile, and connected in series. Through the hollow core of these was run a $\frac{1}{4}$ -in. pipe having a sleeve or other connection on the end to form a shoulder. The length of this was such that when screwed into the fitting on the other end it would pull the coils securely together and form a support free from the casing. The details are so obvious from the drawing that further description is unnecessary. The wires must be well insulated and the joints of the pipe tight to prevent leakage of either current or water. If no asbestos-covered wire can be obtained for the conductors inside the heater proper, it is possible to resort to the method used in this case of cutting glass-tubing (found in any mine assay office) into short beads and stringing them on the wire before insertion. Where it is not possible to get coils of the kind mentioned, one may be made by rolling dampened asbestos board around

in most instances where a vein or orebody is intersected by a fault, the continuation of the ore beneath the plane of dislocation is of lower value than that above the fault, and that this condition was present whether the amount of displacement was great or small. In some cases there was found a decided enrichment of the vein or orebody just above the plane of faulting, although this was not always so. I would like to ask if others have ever observed the apparent influence in this respect of faulting on veins and ore-deposits, and what were the conditions where thus observed? The several instances I have in mind were those where the continuity of the orebody was interrupted by dip-faults rather than those approximating the strike of the vein.

San Francisco, November 20.

ENQUIRER.

HIGH EXPLOSIVES, such as dynamite, nitro-glycerine, and similar compounds may not be legally carried in personal baggage on railroad trains or other passenger vehicles. There is a prescribed maximum penalty of imprisonment for 10 years for anyone convicted of this crime when death or bodily injury results from the illegal transportation of explosives. When no injury results, the maximum penalty is 18 months imprisonment and a fine of \$2000.

MAP OF SOUTHERN BRITISH COLUMBIA, SHOWING THE BOUNDARY REGION.

Electrolytic Refining at Trail

By T. A. Rickard

INTRODUCTION. The Consolidated Mining & Smelting Company of Canada is the owner of the smelter at Trail, the only refinery in the Dominion. This metallurgical establishment is remarkable for producing five metals by electrolytic process: gold, silver, copper, lead, and zinc. Several other metallurgical products are manufactured, such as manganese dioxide, sulphuric acid, hydrofluosilicic acid, and copper sulphate.

The Trail plant was built originally by F. Augustus Heinze in April 1896 for the treatment of the silicious copper output of Rossland and the silver-lead product of the Kootenay region. Heinze constructed the 42-inch gauge railway, 10½ miles long, that connects the smelter with the mines at Rossland. The Consolidated Company, as it is known locally, was organized in 1906 to acquire the smelter and the mines, these including the St. Eugene silver-lead mine in the Slovan district and the Centre Star-War Eagle group of copper mines at Rossland. The railway to Rossland passed into the possession of the Canadian Pacific, which also controls the Consolidated Company. The managing director and general manager of the latter is James J. Warren, who likewise is president of the Kettle Valley railroad, now also a part of the C. P. R. system, although operated as an independent line. R. H. Stewart, one of the most highly esteemed engineers in British Columbia, is consulting engineer and has charge of the mining operations of the company. E. H. Hamilton was appointed consulting metallurgist in January of this year and in October he was promoted to manager of smelteries and refineries. The Le Roi mine was bought from the English liquidator of a former company in 1912. In 1909 a lease and option was taken on the Sullivan mine from the Federal Mining & Smelting Co., the purchase of this valuable property was completed in 1911, on the initiative of Mr. Stewart, then general manager for the Consolidated Company. This will prove a decisive episode in the history of the enterprise, for the Sullivan is proving itself one of the big mines of North America. The immense zinc-lead ore-

body in that mine caused the management of the smelter to erect an electrolytic plant in September 1915. At the time of my visit, in August last, this addition had just started to produce the several metals, illustrating many interesting phases of the newest metallurgy. Of the ore now coming daily to Trail, 1000 tons of low-grade copper ore is obtained from the mines at Rossland, while 600 tons of zinc-lead ore is supplied by the Sullivan. Small lots of lead ore are received from the Consolidated Company's own properties in the Ainsworth district and sundry contributions of custom ore are derived from mines scattered throughout the adjacent mineral territory.

The Trail smelter occupies a fine site, on a gravel terrace, backed by high hills and overlooking the Columbia river, here a lordly stream flowing between granitic slopes. At the time of my visit the supply of labor was inadequate owing to the harvesting operations, for which men had been drawn to Alberta on wages of \$3 to \$4 per day. The War, of course, has taken a good many, especially the better class of operatives and members of the technical staff.

The smelter is not bothered by 'smoke suits,' the Consolidated Company having purchased the adjacent land to avoid this very trouble. Now that the operations of the smelter support a community of increasing size and create a market for agricultural products, the farmers are buying back the land under agreements to which a smoke clause is attached.

The main smelting-plant contains five copper blast-furnaces, four lead blast-furnaces, and two 12-ft. basic-lined converters. All except one of the blast-furnaces receive their charge in cars that are dumped by means of latches released on arrival within the furnace itself. One furnace is charged in the old-fashioned way, through an opening in the charge-floor, after the cover, which is on wheels, is pushed away. This work on the charge-floor of a smelter is among the most unpleasant and it deserves all the attention that the metallurgist can

give to it, for the workman's efficiency, physical and mental, is impaired by the fume and smoke. The fact that the men are "used to it" does not alter the fact that their health and efficiency suffer from the escaping fume and dust. Of course, the lead fume is poisonous, but the sulphurous gas is said to be irritating only. Watching the operations of smelting, particularly in the converter department, one realizes that big-scale operations were impracticable before electric cranes became available for the moving of heavy loads.

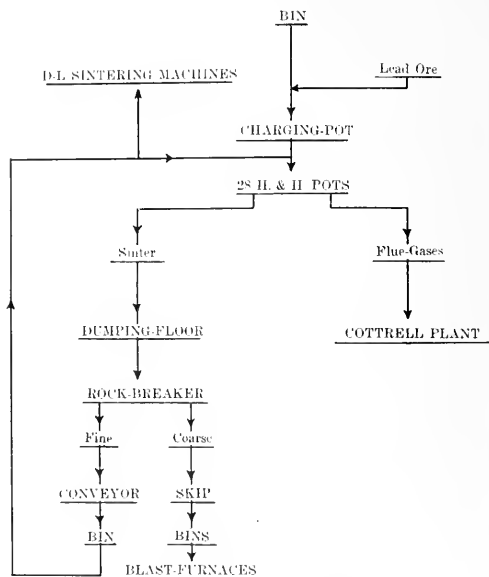

Looking at the interior of a blast-furnace and remembering the great diversity of shape given to this metallurgical unit, one concludes that the shape of a furnace is not so important. It makes its own smelting area.

The distinctive features of metallurgical practice at Trail at the present time are due to the treatment of a large tonnage of zinc-lead ore from the Sullivan mine, which is situated 250 miles north-east of Trail in the East Kootenay district, and about 20 miles north of Cranbrook. It is an old mine, as age is measured in this part of the world, having been opened up in 1888, when it was operated by a local company that built a lead smelter near the mine and went bankrupt. Two or three other companies tried in vain to exploit the mine as a source of silver-lead ore, but the zinc spoiled the operation. The ore is a dense and intimate mineral mixture, part of which appears to be a compound of iron, zinc, lead, and sulphur. Geologically the deposit is an impregnation along the bedding-planes of a flatly dipping quartzite—so I am told by S. G. Blaylock, the assistant general manager. Drill-holes have tested the ore-body for 1400 ft. on the dip, finding a thickness of as much as 140 ft. of ore at the bottom of the bores. The stipes are spread over 3500 ft. on the strike and have an average width of about 40 ft. This is undoubtedly one of the big orebodies of the world and is destined to become famous. An extension of the ore-bearing ground is found in the adjacent Stenwinder mine, which is owned by McKenzie & Mann. The zinc, which formerly was a fatal blemish, has now become an asset, thanks to metallurgical progress and a favorable market.

The Sullivan 'zinc' ore averages 25% zinc, 11% lead, and 3.5 oz. silver per ton, while the Sullivan 'lead' ore runs 14% lead, 12% zinc, and 12 oz. silver per ton. The treatment of the zinc ore is divided into two parts; the ore is roasted, leached, and subjected to electrolytic precipitation, as will be described in detail; then the residue, which contains all the lead and 8 to 10% zinc, is passed to the sintering machines of the lead-smelting department, where it is mixed with lead ores from other sources.

LEAD SMELTING. The Sullivan 'lead' ore is ground to 28-mesh and pre-roasted to 10-12% sulphur in Wedge & Godfrey furnaces, from which it is delivered by a Peck conveyor to a bin made of reinforced concrete. A similar bin receives the leady residue from the electrolytic zinc plant. From these bins the ore mixture is fed into a charging-pot moved by a crane so as to deliver its contents into the Huntington & Heberlein pots, of which

there are 28. Each pot holds 6 to 8 tons. On the bottom a fire of wood slabs is started, and then the ore-mixture is introduced, as described; next the hood is put in place, by the crane, so that the gases can escape into a pipe leading to the Cottrell plant, in which the fume is condensed. The blast being turned on, the ore in the pot is sintered into a porous mass, which is discharged, after 6 to 8 hours, by lifting the pot, by aid of the crane, and moving it to the dumping-floor, where it is tilted and emptied. The lumps are picked up by a 'crab,' or pincers, operated from the crane overhead, and lifted into a large rock-breaker. The fine is taken by belt-conveyor to a bin, where it is mixed with fresh charge and re-sintered either by a Dwight-Lloyd machine or in more 11 & 11 pots; in short, it has to be agglomerated anew,

FLOW-SHEET OF LEAD TREATMENT.

for its finely divided condition renders it unsuitable for smelting in the blast-furnace. The objects of sintering are to reduce the sulphur content and to turn fine material into lumps suitable for the blast-furnace.

Meanwhile the coarse product from the breaker to which the 11 & 11 sinter was delivered is transferred by a skip to the bins above the blast-furnace. A Dwight-Lloyd machine treats material similar to that in the 11 & 11 pots, and treats it in a manner that appeared to me more satisfactory. The 11 & 11 performance looks clumsy; there is much handling of material, too much discharging and lifting. The smoke from the wood-fire and the steam from the wetting of the roasted ore, together with the hammering on the Cottrell tubes, all suggested uneconomic methods. To the technical observer, noise, smoke, and steam do not indicate the last word in metallurgy. On the other hand, the Dwight-

GENERATOR ROOM, ELECTROLYTIC PLANT, AND SUB-STATION.

Lloyd sintering machine strikes the visitor as a clever device, in that the hearth, or 'palette,' is so small and the operation so intensified within a restricted area. At Trail each palette has five interlocking herring-bone grates, so that the interior grates are alternately fixed and loose, causing the sintered ore to detach readily when about to be dumped. This arrangement was designed by Mr. Stewart. It means the saving of six men per day on the two machines.

While the tailing from the zinc-leaching plant now goes to the H & H pots, it is intended to try briquetting, which permits the utilization of scrap-fuel such as coke-breeze, ashes, cinders, and other carbonaceous matter after it has been sized by jigging.

The zinc increases the difficulties of the metallurgist. A 10 to 12% zinc ore makes trouble in lead smelting at

many points—in the sintering, for example. In the lead furnace the atmosphere that reduces the lead oxide also reduces the zinc, which is then volatilized as it descends into the region of high temperature and there resumes its condition of fume, which settles in the upper part of the furnace as zinc oxide, forming accretions that encrust the sides of the furnace and makes growths on the walls, culminating in blow-holes that prevent the uniform settling of the charge. Then follows high temperature in spots, causing the lead to be carried into the flue. The smelter limit on zinc nowadays is 5%. This is about right, but it seems strange to see smelter people making an excess of zinc for themselves; it indicates a notable increase of metallurgical resourcefulness.

ZINC ORE. The Sullivan ore is a dense and intimate mixture of blende, galena, and pyrite. Some of it ex-

BREAKING GROUND FOR THE ELECTROLYTIC ZINC PLANT, OCTOBER 4, 1915. RAILROAD GRADE TO ROSSLAND IN BACKGROUND. SMOKE OF TRAIL REFINERY ON THE EXTREME RIGHT.

hibits a banded structure, the component sulphides being differentiated. In looking at specimens, I was reminded of the equally complex ore produced by the Bawdwin mine, in Burma. The average composition of the ore shipped from the Sullivan mine to the zinc plant at Trail during a month was as follows:

	%		%
Pb	13.8	Al ₂ O ₃	4.1
Zn	22.7	CaO	1.0
Fe	24.0	MgO	0.08
S	23.7	Ag	3.7 oz.
SiO ₂	5.4	Au	Trace

On arrival at the smelter this ore is crushed to $\frac{1}{2}$ -inch and then passed through a cylindrical drier, from which it is elevated to bins that feed two ball-mills, each 5 by 18 ft. and having a capacity of 10 tons per hour. They were made by the Traylor Engineering Works. Thus the ore is reduced so that 90% of it will pass 150-mesh. It is then conveyed by belts to the hoppers in the roaster-building and by these hoppers it is fed to a belt-conveyor that passes to bins above the Wedge furnaces.

ROASTING THE ZINC ORE. Eight Wedge furnaces are in operation, each delivering 40 tons of roasted ore daily. Five more furnaces of the same kind are now nearly completed. All of those in use are being fired with coal, but it is intended to substitute coal-dust as fuel. Each furnace has one hearth for drying and seven for roasting; of these, five have air-cooled arms, or rabblers, while on two hearths the rabblers are water-cooled. The doors are used to regulate the temperature, this having been found advantageous. On each hearth are two rabblers, which make one complete revolution in four minutes, sweeping the pulverized ore toward the centre on one hearth and from the centre on the next hearth, alternately.

The critical stage of the roasting is reached on the second and third hearths, where, if the temperature is allowed to get too high, the charge may agglomerate or clog, forming lumps of partly roasted material having an unroasted core, which therefore escapes oxidation and comes out of the furnace in a sulphide condition. The temperature of roasting is kept as near 1200° F. as possible. If the heat is greater the sulphides burn too rapidly, creating nuclei of still higher temperature and promoting the rapid formation of a zinc ferrite, which is only slightly soluble in acid. The aim, of course, is to roast the zinc-blende to an oxide or a sulphate. The roasted product contains about 3 to 5% total sulphur, of which about one-half represents sulphide and the other half sulphate of zinc. The latter is soluble in water. The oxide is readily soluble in sulphuric acid. Any sulphide in the 'roast' is not dissolved in the acid solution; from the leaching-vats it passes into the tailing, which is accumulated for re-treatment in the lead-smelting department.

Condensation of fume from the roaster is effected in 10 in. Cottrell tubes, yielding an impalpable powder, which is wetted before being removed to the furnace-room, where it joins the rest of the 'roast' on its way to the leaching room. This sublimate leaches readily. I

learn that more recently the Cottrell product is being returned to the roasting-furnace, but it is not yet certain which method is preferable.

LEACHING. The sulphuric acid used in the various departments at Trail is obtained from the gas escaping from the Wedge roasters of the zinc plant and also from lump-burners fed with pyritic ore from the Sullivan mine. These burners are the old kilns or 'stall burners' for burning lump pyrite. They are rectangular in plan and have grate-bars. Charging is done by shovel through a door in the front. The chamber process is employed and 12 to 15 tons of acid is produced daily. This acid is available for parting the doré bars, for the production of hydrofluosilicic acid, and for making the electrolyte in both the copper and zinc refineries.

The hot cinder of roasted ore that comes from the bottom of the furnace is spread upon a revolving table, where it is wetted by a spray and thereby cooled before being delivered to the rubber belt of a conveyor that takes it to the leaching-room. The hot oxidized ore coming into contact with the water-spray is subject to incipient solution. Arriving in the leaching-room the so-called calcine,* is delivered into a launder flowing with water containing 4% free sulphuric acid and discharging upon the first of eight Dorr classifiers. The sand is washed and discarded. The slime-overflow is pumped into a Brown agitator (commonly called a Pachuca tank). In the classifiers the solution becomes nearly neutralized and in the pachuca this neutralization is supposed to be completed. The soluble zinc in the roasted ore is dissolved rapidly: in 10 to 15 minutes. The ferrous iron is oxidized to a ferric state and is eliminated; otherwise the subsequent precipitation of zinc in the electrolytic cell would be hindered and the zinc of the cathode dissolved, causing a rise of temperature in the electrolyte.

The overflow from the pachuca is a chocolate-colored liquor; it goes to a Dorr thickener, and the overflow from this to another thickener, for further clarification, yielding a clear solution, or 'electrolyte,' as it is called already, by anticipation. The feed to the thickeners enters as a 4:1 pulp; the underflow emerges with a 1:1 consistency.

This underflow goes to three Dorr agitators, in which it is mixed with fresh acid in order to remove any undissolved zinc; then the pulp is air-lifted to four acid-proof Dorr thickeners where a counter-current decantation system is employed to wash out the dissolved zinc, the reject being final tailing, containing 12% zinc. It is the aim to lessen this zinc to 8%. The decanted solution goes back to the classifiers. The slime is removed by spigot-discharge and pumped into a settling-pond. The sandy residue, containing 25% lead and 12% zinc, is removed in small cars to the lead smelter. The overflow from the thickeners—a clean solution—is passed through a 6 ft. Hardinge mill, which is kept loaded with

*A term that should be restricted to the product that results from the process for removing carbon dioxide from carbonates, not sulphur from sulphides. That is 'roasting.' 'Calcine' is derived from *calx*, lime.

limestone, for the purpose of precipitating iron. From here the solution is raised by air-lift into a settling-tank, the overflow from which passes to a Kelly filter-press and thence to a pachuca, after which it is agitated with cubes of impure zinc (weighing one pound apiece) in cylinders, 6 ft. diam. and 20 ft. long, in order to remove any copper or cadmium. These cylinders are equipped with baffles. The violent agitation keeps the zinc well scoured. The combined copper and cadmium in the Trail smelter amounts only to between 0.008 and 0.01%. From the cylinders, called 'tumblers,' the solution passes through sacks (30 by 36 in.) made of cheap canvas or 6-oz. duck. These are cleaned weekly. Using 180 sacks, 700 tons of solution is filtered daily.

The above describes the operations as conducted at the time of my visit, last August.

The tonnage of solution going out of the leaching-room is measured by a V-notch weir and a float to which a Bristol disc is attached. The new plant, then being erected, to produce 70 tons of spelter daily, and therefore to treat 1800 tons of solution daily, consisted of 9 Brown agitators, 13 (40-ft.) thickeners, 9 (32-ft.) thickeners, 4 (12 by 60-ft.) storage-vats, besides the filter-presses. This plant is now at work.

The leaching process was in course of experimental development at the time of my visit. It will be interesting to note the changes made in the three months since then. Now the roasted ore is mixed with water containing 6% free acid and is then pumped into the first of an 'acid' series of pachuca, each 10 ft. diam. by 30 ft. high. The overflow from the first goes to a second pachuca, then to a third, and a fourth, in series, finally overflowing to four Dorr classifiers. Here the sand is washed and discharged, while the slime-overflow goes to six 32-ft. Dorr thickeners for counter-current washing. The tailing is discharged. The overflow from these thickeners is air-lifted to the first of four 'neutralizing' pachuca, where high-grade roasted ore is added to neutralize the solution thoroughly and to coagulate any slime. If necessary, a small quantity of ground limestone is added at the last pachuca in order to hasten the settling of slime. The overflow from the last pachuca goes directly to three 32-ft. Dorr thickeners, the overflow from which passes to two Kelly presses, by which it is thoroughly clarified. The filtrate is pumped to two 10 by 30-ft. pachuca loaded with granulated zinc, which serves to precipitate the copper and cadmium. The overflow goes to vacuum-filters that collect this copper and cadmium, leaving a filtrate that is fit to be an electrolyte. The underflow of the neutral thickeners is pumped to the first member of the first, or 'acid,' series of pachuca tanks. Robert Vaughan, the superintendent of this department, states in a recent letter that the three main points in the success of the leaching have been:

1. The designing of an efficient diaphragm pump.
2. Thorough neutralization of the solution.
3. Agitation of the clear solution with granulated zinc to precipitate the cadmium and copper.

On August 17 the daily record showed that 223 wet

tons had been delivered into the leaching-room; the moisture averaged 12%, so that the dry weight was 196 tons. This roasted ore contained 25.5% zinc and 5.9 total sulphur, of which 2.4% was present as sulphate. As regards 'sand,' the heading consisted of 73 tons assaying 25.5% zinc, while the tailing of 64 tons contained 14.2% undissolved metal in the sand itself and 1.6% zinc as dissolved loss in the liquid, so that the total loss was 15.8%, the extraction being 48% only. As regards the slime, the 123 tons of heading assayed 25.5%, while the 108 tons of tailing assayed 14.2% undissolved and 1.4% dissolved, so that the total loss in the slime was 15.6% zinc, or 61%. These results have been greatly improved since then, I am informed. Among the agitators the percentage of moisture was 77.71 and 88; the percentage of acid was 0.42, 0.38, and 0.38, respectively; the percentage of iron in the solution was 0.124, 0.095, and 0.095. Recently this percentage has been reduced to 0.002. In the pachuca the moisture was 88%, the zinc percentage 22.8, the acid percentage zero, the iron percentage 0.013. In the various thickeners the underflow ranged from 41 to 54%, while the acid in the underflow varied from zero to 0.38%. The storage of acid was shown as 619 tons of 3.98%. This was the solution applied to the roasted ore. [It averages now 5 to 5.5%.] The difference between head tonnage and tailing tonnage was 9 tons, in 73 tons, or a little over 12%, which represents the zinc extracted.

This outline of the work in its experimental stage is worthy of record. The 'sand' and 'slime' refer to the coarse and fine cinder in the roasted ore. The extraction of the zinc in the Sullivan ore has been improved to 65% since the time of my visit, so I am informed by Mr. Hamilton, to whom I am indebted for many courtesies.

The zinc oxide and sulphate go into solution quickly; 'they have not to be played with,' remarked Mr. Vaughan, as in the cyanidation of the precious metals. The apparatus used, however, reminds one of a cyanide plant. As regards filtration, it will be interesting to ascertain whether a cake of slime can be made thick enough to hold a vacuum. No barren wash is in use, as in cyanidation. The poorest solution contains 2 to 3%; therefore a filtering effect is essential; dewatering will not suffice. The precipitation of ferric hydrate clogs the classifying apparatus; so also the lead oxide, lead sulphate, and lime sulphate have a cementing quality that is annoying. In the Hardinge mill the lime kills any 'latent' acidity and separates the last of the iron. Thus the lime is a useful precaution.

The pumping of 1:1 slime in slightly acid solution is hard on the metal bearings of pumps. The solution is never perfectly neutral. The sulphate of lead made by the action of the acid on lead oxide—as also the gypsum analogously made—tends to be sticky if allowed to settle, as happens during any temporary break-down in the plant. Any difficulty in pumping arising from this cause has been overcome now by the use of diaphragm pumps.

(To be Continued)

CACHE CREEK, ALASKA.

A MAKE-SHIFT SAW-MILL.

The Cache Creek Dredge, Alaska

By Sumner S. Smith

During the past spring the Cache Creek Dredging Co. installed a dredge on Cache creek, which is the first serious attempt at this type of mining in this part of Alaska.

Cache creek is about midway between the Yetna and Susitna rivers, 65 miles from McDougall, a small settlement on the Yetna. It is a tributary of the Kahiltina from the north, the latter flowing into the Yetna 25 miles above its junction with the Susitna. Stern-wheel steamers can run up the river to McDougall, from which point a wagon-road has been made along the east bank of Lake creek to the Kahiltina, where a bridge has been built by the Alaska Road Commission. From this point the summer trail follows the higher ground on the western side of the Peters hills, although the marshes and bogs are so frequent that it is practically impossible to do any freighting over it during the summer. In the winter the road from the bridge follows the river and the northerly bank to Cache creek and then up the creek. The Alaska Road Commission sent an engineer over the district this summer, investigating the possibility of improving the present trail or of building a new trail from Talkeetna, on the Susitna river. The latter route would shorten the haul and it is probable that the Government railroad will be completed to this point during the summer or fall of 1917, permitting a better freight rate than can be obtained at present. The district warrants this consideration, as freighting is impossible over the present summer trail, but the Road-Commission appropriations have been so limited that it has been impossible to serve all districts, however meritorious.

The Cache Creek valley lies between the Dutch and Peters hills and is comparatively narrow in the upper portion, where the dredge is at work. The bedrock is

slate, graywacke, sandstone, and shale with occasional beds of lignite. In referring to this district, Capps states (U. S. G. S. Bull. 520, p. 179): "Next younger in age than the slates are the diorites and granites, and associated dikes of the high range. These cut the slates and so are younger. The slates have undergone contact metamorphism near the large intrusive masses, and the abundant veins and stringers of quartz that are present for several miles from these bodies are probably the source from which the gold of the placer districts is derived."*

The dredge equipment and timber were assembled at Seattle in June, 1915, and towed to Anchorage on the old sailing-vessel *Garden City*. The stern-wheel steamer *Lois* was also built at Seattle and brought to Anchorage at the same time under her own steam, as the facilities for handling barges across Cook inlet and up the Susitna and Yetna rivers were totally inadequate at that time. At Anchorage, the equipment was transferred to barges that were pushed up the Susitna and Yetna rivers to McDougall. Here the dredge-timbers were framed and during the following winter (December to April) the entire outfit was hauled on bob-sleds from this point to Cache creek, 12 miles above its mouth, where the dredge was assembled this spring and started operations on July 7.

The creek is comparatively shallow, the average depth being approximately six feet, so the dredge was built with a large hull to secure a shallow draft. It is 87 ft. long, 54-ft. beam, and 7 ft. deep. The planks on the bottom are 4 by 12, those on the sides 6 by 12 and those on the deck 3 by 12. The winch-deck is 30 ft. above the main deck, and the pilot-deck 12 ft. above this.

*Note the unnecessary plurals in this quotation.—EDITOR.

There are sixty-five 7-cu. ft. close-connected buckets with manganese-steel lips; and, while the dredge has a capacity of 3000 cu. yd. per 24 hours, the management has based its plans on 2000 cu. yd. only, on account of the shallowness of the ground and the number of boulders. Though the latter have retarded the speed of digging, they have not proved a serious hindrance, as they

Power is furnished by a 250-hp. Yarrow tubular boiler, burning coal, which is mined locally. A 150-hp. Reaves engine drives the pumps and dynamo, a 125-hp. Lidgerwood the digging-ladder, and a 20-hp. the winches. The steam from the engines is condensed and returned to the boiler.

A number of beds of lignite outcrop on Cache creek and its tributaries, and from these an ample supply of fuel may be obtained at a low cost. The company has secured a free-use 10-acre permit to mine coal and this summer obtained its supply from an open-cut two miles from the dredge. This haul will be obviated the coming season, as a contract has been let to drive entries and to open rooms on a 5-ft. bed on Cache creek during the winter, so a supply will be easily available at a convenient point in the spring. The coal has a long flame and is good for making steam, though the percentage of ash is high. If the company had not owned the steam-equipment before the construction of the boat was planned, the situation would have been ideal for an electrically-operated dredge, the power being generated at

the point where the coal was mined.

After a short, though successful season, the only change planned on the dredge is to add a second bull-wheel so that the drive will be on both sides of the bucket-line, which it is believed will reduce friction and

are not large enough to require special apparatus for handling them. With the present number of buckets, the dredge will dig 30 ft. below the water-line, though it is improbable that it will be called upon to work at anywhere near this depth on this portion of the creek.

The fine gravel from the buckets falls through an 11-in. grizzly into a 48-in. flume, 108 ft. long. The grade of the flume is adjustable, though the best results are obtained by keeping it at an inclination of about 1½ in. per foot. The riffles are 2 by 4's, capped with ¾-in. manganese-steel plates and are set 1¾ in. apart. A 6-in. centrifugal pump supplies wash-water at the grizzly and an 18-in. centrifugal pump discharges directly to the flume. The buckets are washed clean by water from two nozzles, the gravel falling to a save-all sluice equipped with Hungarian riffles. This flume is 18 in. wide set on a grade of one inch per foot.

A feature never previously used on an Alaskan dredge is the construction of rock-chutes from the grizzly. The oversize from the bars goes to a Y, the branches of which pass on each side of the save-all sluice and empty in the pond aft of the dredge, where the stones form a dam and prevent the fine from filling the pond under the boat. These chutes are 42 in. wide and lined with manganese-steel plates at the points of greatest wear.

give the dredge a marked increase in efficiency, with a corresponding decrease in operating cost.

THE CONSUMPTION OF POTASSIUM CYANIDE by the mills of the Black Hills in 1915 was 11,477 lb. and of sodium cyanide 485,300 lb. It required 13,900 lb. of quicksilver to supply the gold mills, nearly all of which was used in the Homestake mills.

THE CACHE CREEK DREDGE.

NECESSITY IS THE MOTHER OF INVENTION.

A Matter of Principle

The following is an excerpt from the minutes of the meeting of the Board of Directors of the American Institute of Mining Engineers, on November 24.

MANUSCRIPT OF W. H. SHOCKLEY. The Pennsylvania Anthracite Section, through Vice-Chairman Edwin Ludlow, presented the answer of that Section to the criticism of the San Francisco Section. The following resolution was then passed:

WHEREAS, this Board of Directors on June 23, 1916, instructed the Secretary to telegraph Mr. Durand, the Chairman of the International Engineering Congress, as follows:

"Voted that it is the sense of this meeting that if the paper of W. H. Shockley to the International Engineering Congress which has been objected to cannot be changed to meet the views of the Pennsylvania Anthracite Section, it should not be published."

Now Therefore be it Resolved, that the Directors of the Institute regret that the language of the above message was considered unwarrantably mandatory in tone and assure the San Francisco Section that there was no intent on their part to arbitrarily censor, or cause to be censored, Mr. Shockley's paper, and refer the Section to the letter of President Ricketts to C. W. Merrill, dated November 25, 1916, which is hereby approved. [This letter follows.]

12 Broadway, New York City,
25 November, 1916.

C. W. Merrill, Esq.,
121 Second Street,
San Francisco, Cal.

My dear Mr. Merrill:

I feel, and have always felt, that Mr. Shockley's intent is not to be impugned, and I have never questioned his good faith in presenting the figures he did, but I did feel that he was not, and is not, personally thoroughly familiar with the anthracite district. On the other hand, I am inclined to put great weight upon the statements of eminent engineers of like high character, bearing on matters of fact in their own particular field.

After investigation I felt, and feel, that the figures quoted by Mr. Shockley are not average figures, and while official in that 'in the catalogue' they go as such, they are not really representative, and other figures are available and could have been found which are representative and official.

I readily admit that the form of our resolution was crude, badly expressed and not in accordance with the thought we intended to convey, and I for one will be very, very glad to see it withdrawn. What I thought we were saying was that in our opinion the figures in question did not represent the facts, and that therefore they should not in our opinion be published. I thought from Mr. Shockley's and Mr. Durand's letters, which you have, that this matter had been adjusted satisfactorily, and as you know, Mr. Shockley permitted his paper to be published and expressed his acquiescence in having it published in its present form.

Personally I feel very deeply the criticism of the San Francisco Section. I feel that we are culpable to a certain extent. We have been careless in form rather than in fact, and are to blame. On the other hand, I regret a certain cynicism and lack of faith in me and my associates, shown by the resolution

of the San Francisco Section, giving me and the parent institution no chance of a previous explanation before condemnation, and I believe that my good friends and associates, including Mr. Shockley, for whom I have the highest regard, will upon consideration see the justice of my position.

Yours very truly,

L. D. RICKETTS,
President.

The foregoing was presented by Mr. Merrill to the San Francisco Section at its regular monthly meeting on December 12; whereupon the following resolution was passed unanimously:

"Voted that having heard the resolution of the directors of the Institute, including the friendly message from our President, we appreciate the expression of regret, we desire to reciprocate the goodwill indicated thereby, and we are glad that the incident is now satisfactorily closed."

MINE VENTILATION has an important bearing on the cost of producing ore. Impure air, together with excessive heat and high humidity, not only seriously affect the efficiency of the miner, but they may impair also his health and safety. These facts are of sufficient importance to warrant the close attention of every metal-mine operator who wants to reduce his costs to a minimum. In recent years this subject has been given much thought by large metal companies in various parts of the United States. Many of them now employ men whose chief duty is to see to the proper ventilation of the mine. In many cases fans have been installed, at great expense, in order to secure better ventilation. The following case will serve to illustrate how the cost of production may be increased through poor ventilation; according to the investigations of the U. S. Bureau of Mines: A certain large mine produced approximately 1000 tons of ore per day at a cost of \$1000. The labor cost was \$750. The working-places from which 300 tons of this output came were poorly ventilated. On account of the poor air and the heat in this part of the mine (85 to 90° relative humidity 95 to 100%), it was estimated that the miners put in only one-half of their time in effective work. These miners would have produced 600, instead of 300 tons, had conditions been normal, thus increasing the total production of the mine to 1300 tons per day. This would have reduced the labor cost from 75 to 57.7c. per ton. This illustration is conservative. In a great many deep mines an even greater saving could be effected through improved ventilation.

MOLYBDENITE, the di-sulphide MoS_2 , is the only molybdenum mineral of importance. It contains 40% sulphur, the remainder metal. The mineral belongs to the acid-forming elements, and frequently occurs in granite, though also known in limestone, schist, and other rocks.

Plant of the Babilonia Gold Mines, Nicaragua

By S. M. Parker

CRUSHING. The ore is delivered to the mill-bin from the mine in cars of 1500 lb. capacity. It is iron-stained quartz containing fine free gold, invisible except in some of the high-grade. This ore is about half clay and half rock, so that in the wet season it is difficult to handle on account of its excessive moisture.

The ore is dumped over two grizzlies with 2½ in.

lasts about three months. These pawls are made at the mine and cost very little.

The mills are two No. 3 Holman pneumatic stamps, consisting of a stem or piston carrying a boss-head and shoe, and working in a cylinder hung by two arms from a crank-shaft. In the walls of the cylinder are four rows of holes, two above and two below the centre position of the cylinder. When working with a new shoe, rows two and four are plugged and as the cylinder travels up and down it traps air between the piston and cylinder-head. This air on the return stroke is compressed, acting as a cushion, and also assists in the propulsion of the stem. As the shoes and dies wear, the plugs are changed to rows one and three. The stamps drop 145 to 150 times per minute, depending on the class of ore.

Cyanide solution is fed to the mortar-boxes around the stem in a shower, which helps to keep the sand out of the lower guides. In order to increase the tonnage it was found necessary to add solution to the throat of the mortar-box. The ratio of solution to ore is 9:1, 1.6 lb. sodium cyanide and 0.5 lb. lime per ton, and \$1.56 gold per ton. Lime is added in the mill-bin at the rate of 10 to 15 lb. per ton of ore.

The screens used are the Tyler double-crimped steel-wire of 6, 7, 8, and 9-mesh, as needed. The average stamp-duty per 24 hours from August 1915 to May 1916 was 25.08 tons. From January 1916 to May 1916 it was 27.84 tons.

Mortar-liners last about 4 months; stems, 3 months; and screens, 3 days. The wear of shoes is 0.48 lb. and of dies, 0.17 lb. per ton of ore crushed.

SCREEN-ANALYSIS OF BATTERY-PULP

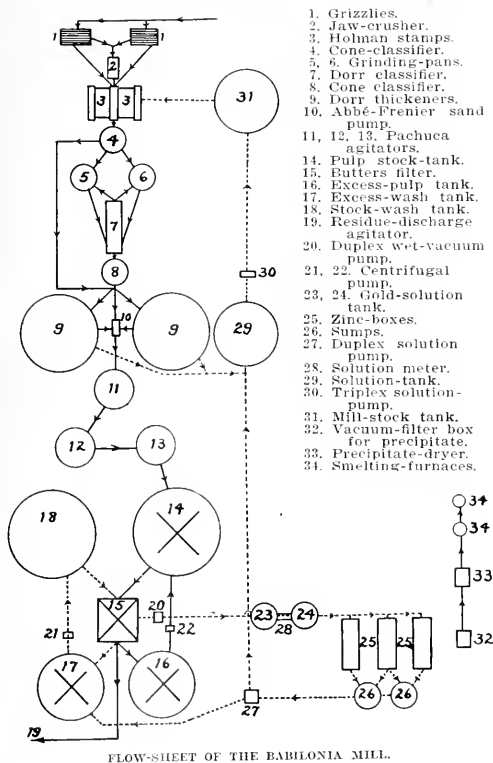

Mesh	By weight,		Value	
	%		per ton	proportional value per ton
20	50.63		\$10.00	\$5.063
40	15.95		8.80	1.403

200	11.90		8.80	1.047

\$8.978

66.58% by weight is coarser than 40-mesh and contains 72.02% of the gold.

GRINDING AND CLASSIFICATION. The battery-pulp passes through wooden launders to a pointed box with an ascending stream of solution, which separates about 20% of the fine in the overflow, which passes direct to the Dorr thickeners, the underflow going to the grinding-pans.

The grinding equipment consists of two 5-ft. Fraser

spacing, the oversize passing through a 10 by 19-in. Gates jaw-crusher, set to crush to 2½ inches. The crushed rock joins the fine in the bin. The crusher consumes 6 hp. and has had only one set of jaw-plates in 10 months.

STAMPING. The crushed ore is fed to the stamps by two suspended-type Challenge feeders. Originally these were equipped with the Dale patent friction-feed, but on account of not being able to handle the wet ore they were equipped with a pawl, gripping on the edge of the friction-wheel. This arrangement has given entire satisfaction, the only wearing part being the pawl, which

& Chalmers pans making 54 r.p.m., and fitted with Free-man's classifier-overflow.

SCREEN-ANALYSIS OF PAN-DISCHARGE

Mesh	By weight, %	Value per ton	Proportional value per ton
20	5.96	\$13.40	\$0.798
50	6.50	9.04	0.588
60	12.98	6.20	0.805

80	8.21	5.50	0.452
100	18.78	5.50	1.033
150	11.33	7.70	0.872
200	3.04	14.80	0.450
- 200	19.31	14.50	2.800

\$8.562

The pans require 7.5 hp. each. A set of shoes and dies lasts from 24 to 26 days. Wear of shoes is 3.22 lb. and of dies 4.41 lb. per ton of ore. The consumption of metal is excessive as the shoes and dies do not wear evenly. From 1½ to 2 in. of metal remains in the dies when the shoes are entirely worn out. A new set of shoes is sometimes used with the old dies, the shoes requiring about three sets of old dies. However, using them in this way causes excessive loss of time in changing dies and grinding a poor surface. New models have been made, having more metal in the shoes and less in the dies, and it is expected that these will wear evenly.

When shoes and dies are new the return-sand to be re-ground is about 5%, increasing to about 15% as the pans wear. The pans discharge to a simplex Dorr classifier, which returns the sand and delivers the slime to a 5-ft. cone.

In order to overflow as much—60 mesh material as possible, the rake was raised and run at the rate of 24 strokes per minute. A spray was also added to help separate the fine.

SCREEN-ANALYSIS OF CLASSIFIER-PRODUCT

Mesh	Feed	Sand	Slime
	By weight, %	By weight, %	By weight, %
40	0.21	3.42	0.20
50	2.71	6.47	1.45
60	5.85	18.75	3.87
80	15.60	35.55	14.32
100	19.05	26.12	15.35
120	4.38	3.20	3.57
120	50.13	6.11	60.85

The overflow is good, but the sand still contains 28.61% of minus 60-mesh product.

From the 5-ft. cone, receiving the overflow of the Dorr classifier, the underflow goes to an Abbé-Freder sand pump, and the overflow to the Dorr thickeners. The object of this cone is only to remove the coarse sand and avoid sending it to the thickeners.

The Dorr thickeners are two 9 by 17 ft. tanks with an area of 454 sq. ft. The speed of the rakes is one revolution in five minutes. Settled slime is drawn intermittently with an average specific gravity of 1.40. This slime is passed to the sand-pump before mentioned and joins the sand from the cone, being then elevated to the Pachuca tanks, or Brown agitators.

The clear overflow from the thickeners carrying an average of \$1.14 is pumped back to the mill stock-tank by a 6 by 8 in. triplex pump.

AGITATION. The Pachuca tanks are three 8 by 32-ft. tanks connected for continuous treatment. The specific gravity of the pulp averages 1.42; it is agitated for 24 hours.

Cyanide strength is maintained at 24 lb. NaCN per ton of solution, by adding solid cyanide in a basket under the overflow of the air-lift. Air-pressure is maintained at 21 lb., each tank using 28 cu. ft. of free air per minute. Consumption of cyanide is 0.7 lb. per ton of ore.

From the agitators the pulp passes to a 20 by 6-ft. stock-tank equipped with a mechanical agitator.

FILTRATION. The filter is a 21-leaf vacuum-filter plant, constructed on the gravity-system and having a filtering-area of 1890 sq. ft. The vacuum is maintained at 21 inches by a 7½ by 7-in. duplex wet-vacuum pump, requiring 5 hp. This pump has done good service for nearly two years, two valves being replaced but once in this time.

The average thickness of cake obtained is 1½ in. A 2½-in. air-lift is used to keep the sand from settling, discharging to a distributing-laundry. In order not to crack the cake on transferring pulp and wash-water, the vacuum is reduced to 15 in. No water-wash is used. To discharge the cake, water and air are blown-in together. The cakes fall into a cement tank with a revolving-arm agitator, which mixes the pulp with enough water to discharge it to the river.

FILTERING CYCLE

	Minutes

Filtration	32
Emptying	3
Filling wash-solution	3
Wash period	134
Discharge	15
	190
	Cents
Value of wash-solution	7
Effluent wash at end of 90 minutes	34
Effluent wash at end of 120 minutes	10

The average life of the leaves is 12 months. They are treated in a 1% hydrochloric acid solution, four leaves being changed every week. Consumption of acid is 0.19 lb. per ton of ore treated. One man spends half his time repairing and washing the leaves.

The pulp in the residue-agitator is agitated 45 minutes, its volume and specific gravity being measured. From these data the daily tonnage is calculated.

PRECIPITATION. The pregnant and wash-solutions are measured by a meter and go to two 12-ton gold-vats, each containing four filter-leaves, filtering by gravity.

Solution is then distributed to pass through three zinc-boxes, each containing nine compartments, and is precipitated on zinc shaving. Approximately 170 tons of solution is precipitated daily, or 1.5 tons of solution per cubic foot of zinc. Consumption of zinc is 0.5 lb. per ton of ore.

FRONT AND END ELEVATION HOLMAN PNEUMATIC STAMPS SHOWING CONCRETE BATTERY-BLOCKS.

The barren solution is run partly to the wash-circuit and the remainder pumped by a 5 by 15-in. duplex pump to join with the overflow of the thickeners, where it is pumped to the mill-stock tank.

Boxes are packed every 3 to 5 days, moving the zinc up to the head compartments and adding new zinc in the lower ones. Average value of barren solution is 9c. per ton.

CLEAN-UP AND SMELTING. The precipitate is collected at the end of every month and filtered on a vacuum-filter to about 25% moisture. It is then dried, fluxed, and smelted in two oil-burning furnaces.

FLUX

	Parts
Precipitate	100
Carbonate of soda	20
Borax glass	25
Sand	2

The smelt requires from 14 to 16 hours.

The slag produced is granulated and amalgamated in a small barrel, the resulting amalgam being added to the next month's smelt. The residue from amalgamation is assayed and kept for future treatment. Average value of slag after amalgamation is 92c. per pound.

Experiments have proved that by agitating five days in a solution of 6 lb. of cyanide per ton, an extraction of 70 to 75% can be obtained. This method of treatment will probably be followed in the future.

SAMPLING. Battery-head samples are taken every half-hour from the feeders. Every eight hours the sample obtained (about 200 lb.) is crushed and quartered to a suitable size for the assayer. The daily head-value is calculated by multiplying the time run by the assay-value and dividing by the total time run.

Samples are taken from the residue-agitator-tank at every discharge of the filter. In order to obtain an average sample the valve is opened and a small can is used to dip out a portion of the stream, from time to time,

until a five-gallon oil-tin is filled. This sample is mixed thoroughly and the specific gravity determined. Every eight hours this sample is changed, its specific gravity taken, filtered, and washed. The filtrate is assayed for soluble gold and the washed cake for insoluble. The value of the residue is the number of tons of dry pulp, multiplied by the assay-value of the undissolved per ton, plus the tons of solution in discharge, times value of the soluble gold, the total being divided by the tonnage treated.

Solution samples are taken at the top and bottom end of the zinc-boxes. On packing the zinc-boxes at the close of the month, a sample of zinc returned to the boxes is assayed.

The 'gold recovered' is the sum of the bullion produced, plus the value of zinc replaced, plus values of pulp and solution in circulation, plus value of slag.

The 'gold called for' is the assay-value of the ore, less the residue-value, plus the value of the zinc, pulp, solution, and slag of the previous month. The difference is the over or under-production.

POWER is furnished by three 25-hp. suction-gas engines and one 60-hp. engine. In the wet season a Pelton water-wheel furnishes about 35 hp. There are two gas-

producers burning charcoal, one only being used at a time.

(GENERAL REMARKS. It was shown by the experimental work that crushing to pass 60-mesh gave the most economical results. Finer grinding will reduce the value of the residue somewhat, but the increased cost of grinding will more than offset this gain. The plus 60-mesh product in the residue averages 1.6% by weight for the last 10 months.

Extraction is shown as follows:

	Extraction, %
Battery	1.0
Pans	5.0
Dorr thickeners	38.5
Agitators	49.0
Filters	1.0
Total	94.5

The Holman pneumatic stamp is an excellent mill for coarse crushing, although the capacity decreases rapidly when using screens finer than 12-mesh. It is a good machine for small properties where freighting is done by animals, no part being excessively large, especially in the No. 3 mill with its built-up mortar-box.

A total of 1615 tons of ore was treated.

A Local Magnetic Pole

The magnetic poles of the earth are commonly supposed to be diametrically opposite each other, and that a line through the earth connecting them would necessarily pass directly through the earth's centre. Such, however, is not the fact, for a line connecting the north and south magnetic poles passes beneath the Pacific Ocean and about 750 miles to one side of the centre of the earth. The north magnetic pole is on the west coast of the Boothia peninsula, opposite the north point of King William's Land, an island, just above latitude 70° north and longitude 95° west. It is interesting to know that there is a centre of magnetic attraction—a local magnetic north pole, at Treadwell Point, near Juneau, Alaska. Observations were made there in 1900 and again in 1907. A tent was erected at a spot where the dipping-needle stood vertical with its north end down, and the compass

reversed its direction when carried from one side of the tent to the other. Ship's compasses, a mile away, in Gastineau channel, are deflected about 11° by this local magnetic attraction.

SUCCESS IN SMELTING requires a careful study of the slags. If the slags are suitable the smelting operations are likely to prove successful. The things to be carefully considered and watched are the melting-points of the various constituents of the charge; these determine the amount of fuel necessary; the viscosity of the slag, which is important, as it must be low or the valuable minerals in the form of matte, speiss, or metal, will not readily separate from the earthy minerals of the charge. The chemical composition of the slag must be such that it will not dissolve large quantities of the valuable metals present in the ore, and occasionally it is required to remove detrimental substances from the charge.

Gold Mining in Korea

By E. W. Mills

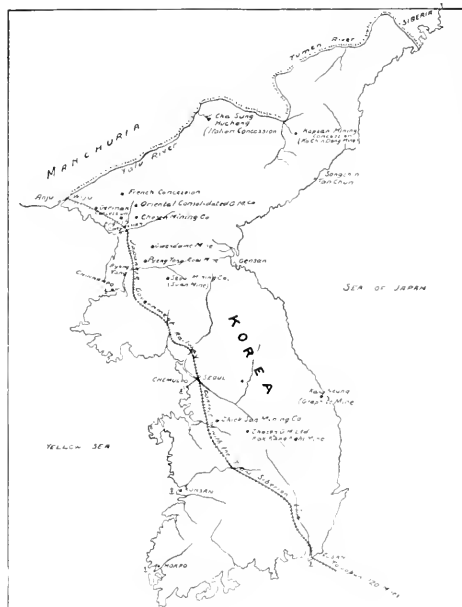

*In the course of a long paper contributed to the Korean branch of the Royal Asiatic Society, the history and present position of gold mining in Korea was given. The author has personal knowledge of all the gold districts during 13 years' experience, and from a personal connection with the three chief gold-mining companies, the Unsan, Suan, and Chiksan. The Unsan mines are situated in North Pyengan, 40 kilometres south of the Yalu river. The Suan mines are situated some 100 kilometres farther south, about the middle of south Pyengan, while the Chiksan mines are situated about the same distance farther south in the province of Kyong-Ki, adjacent to Namyang bay.

The development of production in recent years has been rapid. In 1895 the output first passed the £100,000 mark, while in 1913 it was valued at £1,035,391, in 1914 £1,023,398, and last year it attained the record yield of £1,229,621.

Gold mining is of ancient origin in Korea, going back probably before the Christian era. This branch of mining, however, was entirely alluvial, and it has been overshadowed of late by the development of lode mining under modern conditions. The first concession to foreign engineers was the Morse in 1895. Subsequently, concessions were granted to British, German, French, Russian, Japanese, and Italian representatives. The following is a short account of the leading mines now operating:

UNSAN CONCESSION. This property is being worked by the Oriental Consolidated Mining Co., an American company, which has been highly successful in its operations in this district from the beginning. Operations were first started at Chittaballie, and a 20-stamp mill was placed in operation in 1897. This mill was the pioneer of the modern stamp-mills in Korea. Before the mine was abandoned, in 1905, it had produced 152,632 tons of ore, valued at ¥3,036,952. In 1899 a 40-stamp mill was erected at Tabowie, and in 1907 was enlarged to 80 stamps. To June 30, 1915, this mine has produced 1,226,859 tons of ore, valued at ¥15,918,755. A 20-stamp mill was erected at Kuk-San-Dong in 1900. It was increased to 40 stamps in 1905. This mine was closed down on January 15, 1915, after having produced 551,892 tons of ore, valued at ¥4,788,182. In 1902 a 40-stamp mill was placed in operation at Maibong. To June 30, 1915, 412,071 tons of ore, valued at ¥5,967,274, has been produced. In 1903 an 80-stamp mill was erected at Taraeol. To June 30, 1915, this mine has produced 1,173,208 tons of ore, valued at ¥13,749,526. There are 16 batteries of five stamps each, and 32 vanners of the

Frue type. The daily capacity of this mill is 350 tons. In 1908 a 10-stamp mill was placed in operation at Candlestick. From this mine 43,998 tons of ore, valued at ¥999,591, has been produced up to June 30, 1915. As may be seen from the foregoing, the growth and development of this concession has been exceedingly satisfactory. On July 1, 1915, a total of 210 stamps was in operation at the following mines: Tabowie, 80; Taraeol, 80; Maibong, 40; East Candlestick, 10. The amount of ore crushed for the year ended December 31, 1915, was

295,379 tons, valued at ¥3,758,135. From this ore, gold in bullion and concentrate was recovered to the value of ¥3,228,941. The total tonnage of ore produced from the various mines since 1897 to December 31, 1915, has been 3,986,772, valued at ¥49,568,632. The first dividend of 5% was paid in 1903. Since that time to July 1, 1915, total dividends have amounted to 150% of a total of ¥12,871,550.

SUAN CONCESSION. This British concession is held by the Korea Syndicate, Limited, of London, but is being operated by the Seoul Mining Co. This concession is being developed with highly successful results. Although not as old as the Unsan, its tonnage and output are increasing yearly. It shows promise of eventually becoming the largest producer in Korea. The first mill of 20

*Abstract from London Mining Journal.

£1 = \$4.85.

¥1 = 50 cents.

stamps was placed in operation in the latter part of 1909 at the Suan mine. This mine developed satisfactorily, and the mill was increased to 40 stamps in the autumn of 1911. During the past three years a larger mine than the Suan mine has been developed at Tul-mi-chung, six miles south of Holkol. A reduction plant, the pioneer of its kind in Korea, was placed in operation late in September 1915. This plant has a rated capacity of 350 tons in 24 hours, and is the first one in Korea to use Hardinge ball and pebble-mills, in place of ordinary gravity stamps, for crushing and grinding ore. Both plants also employ the oil-flotation process for the recovery of concentrate. It is expected that the production of gold from the Suan concession for 1916 will approximate a total of Y2,500,000. For the year ended December 31, 1915, the Suan concession produced 108,078 tons of ore, valued at Y1,789,224. The gold production for the same period amounted to Y1,435,041. Since the date of the commencement of milling operations in 1909 to January 1, 1916, the Suan concession has produced 433,361 tons of ore, valued at Y7,945,328, with a total gold production of Y6,566,244. Dividends for the same period amounted to Y2,180,987, or a total of 275%.

CHIKSAN CONCESSION. This concession was operated intermittently by the concessionaires, Shibusawa-Asano Mining Partnership, on a small scale until 1906. In this year American partners were admitted, and in 1907 a small stamp-mill was placed in operation. In 1911 a re-organization took place, whereby the control of the concession rights was taken over by an American company, the Chiksan Mining Co. During the Japanese régime considerable work was done on the placer deposits, and a small profit was made. Although no exact figures are available, it is probable that the alluvial gold production during this time amounted to over Y300,000. For the year ended December 31, 1915, the production of gold from this concession was Y933,261. It is estimated that the Chiksan concession has produced Y3,199,073 in gold, and has treated 192,141 tons of ore during the period from February, 1908, to January 1, 1916. This concession has now reached the dividend-paying stage, and is being operated successfully. The present company has proved the existence of a large acreage of ground containing sufficient gold to warrant the installation of a gold dredge at Sei-go-ri, which was worked earlier under the supervision of the Japanese concessionaires. The order has been placed for this dredge, and it is expected that it will be in operation before the end of 1916. Chiksan will, therefore, have the distinction of starting the first gold dredge in Korea. The operation of this boat, in conjunction with the present mill of 10 stamps, should result in showing considerable increase in the gold production for 1916 and for several succeeding years. It is probable that some monazite may be recovered by the dredge.

JAPANESE ENTERPRISES. Under Government encouragement an important combination was formed in recent years known as the Furukawa Partnership Co., which holds some 15,000 acres in the Koo-Sung district, north

Pyengan. The chief interests comprised are those of Messrs. Furukawa, Asano, and Kuhara. In co-operation with this company, the Kuhara Mining Co. of Osaka, lately completed a smelter at Chin-nam-po, designed primarily to treat gold-copper ores, more especially the concentrate, from the Suan mines.

GOVERNMENT MINES. The Japanese government has itself retained a number of gold prospects for experimental working in different districts.

In all, about 50,000 Koreans and several thousand Chinese and Japanese are now dependent on the foreign companies for their livelihood. The author states that Japanese authorities are willing to assist foreign mining companies in every possible way. After the occupation of Korea, mining regulations were issued in 1906, with further amendments in 1907 and 1908, and a further revision is expected to be published shortly. Henceforth it is provided that "none can enjoy mining rights other than subjects of the Empire or juridical persons organized in accordance with the laws and ordinances of the Empire." It is stated, however, that foreigners who already possess mining rights will not be affected by the revision either now or in the future.

The author concludes that the outlook for a continued increase in gold production is promising, more especially from the successful development of large, low-grade auriferous deposits.

MINE TIMBERS submerged in water will endure indefinitely. This fact is being demonstrated at the Anador Consolidated mine, at Sutter Creek, California, where the timbers of the shaft near the 1000-ft. level are found to be as sound as when put in place nearly 40 years ago. The mine has been idle about 35 years, the workings during this time having been filled with water, which has preserved the timber. The heavy swelling-ground that ordinarily so quickly crushes the timbers in the mines of the Mother Lode in Anador county has little effect when the workings are flooded. This seems to prove that the swelling of the rock is due to exposure to the air, otherwise the process would continue when submerged in water. It suggests that the swelling of the ground that is the cause of so much expense might in some measure be prevented if the surface of the rock, in drifts and shafts, for instance, were plastered with a cover of cement-mortar soon after its first exposure to the air by the advance of mining work.

MOLYBDENITE is used in the manufacture of ammonium molybdate, a chemical reagent employed in the laboratory in the determination of phosphorus in iron ore, the products of the iron furnace, and in fertilizers. The metal molybdenum is added to steel in order to make it self-hardening. From 5 to 10% of molybdenum raises the elasticity and tensile strength of steel, and gives it greater toughness. The tensile strength of molybdenum-steel wire is stated to be from 200,000 to 270,000 lb. per sq. in., that of tungsten-steel 480,000 to 580,000 lb. to the square inch.

Analysis of Molybdenum Ores

By H. Westling and Carl Andersen

The analysis of molybdenum ore presents several difficulties as yet not thoroughly discussed in the literature on the subject and we have been compelled to work out a method of our own which, so far as we have ascertained by actual practice on many ores from various parts of the country, is satisfactory.

For the purpose of our work with the U. S. Molybdenum Co., we found it necessary to have a method of analysis that would give a quick and accurate return, not only of the molybdenum but also of the constituents that usually accompany molybdenum. These are silicious residue, copper, iron, and not infrequently lead and bismuth.

Two difficulties had to be overcome if any reasonable degree of accuracy was to be reached. The first was the peculiar behavior of molybdenum to hydrogen sulphide in acid solution. We found that the one essential to complete precipitation of the metal was hexavalency. It seems, however, as if a small amount of molybdenum would be reduced to lower valency simultaneously with the precipitation of the greater part as MoS_3 . Especially will this happen if iron is present in the solution. Mellor recommends precipitation under pressure, but even this, although satisfactory in the absence of iron, is not quite complete in one operation when iron is present.

The second difficulty was the separation from copper. This seems impossible to effect when it is in the sulphide state. Pure sodium-sulphide solution will separate copper completely from the arsenic group of sulphides, to which molybdenum belongs. When we tried this, we found that copper misbehaves in this particular respect when molybdenum is present. After trying several methods we adopted the one below described. This has the advantage of effecting the separation at the very time of titration for molybdenum.

In the description of our method, we have made references to the general scheme of analysis used in the Rankin-Westling laboratory.

Our method is as follows: Dissolve 2 grams of the sample in 20 cc. HNO_3 , 20 cc. HCl , 20 cc. H_2O . After main action has ceased—usually after 10 to 15 minutes boiling—add about 20 cc. 60% H_2SO_4 , and evaporate to copious white fumes. Proceed in the usual way for lead sulphate and silicious residue.

The filtrate from lead sulphate and silica should now be boiled with a few crystals of ammonium persulphate (to oxidize a small quantity of lower valency Mo up to hexavalent Mo). Boil a few minutes to destroy persulphate, then cool, and precipitate with H_2S . After one hour of brisk current of H_2S in cold solution, discontinue the H_2S and boil the solution a few minutes. Then filter the H_2S precipitate. Wash with previously-boiled cold

water containing $\frac{1}{10}$ of H_2S water. Treat the filtrate as later described, and the precipitate as below:

Rinse the bulk of the precipitate into a beaker with water. Wash the filter-paper with dilute boiling aqua regia (1 part HNO_3 , 1 part HCl , 3 parts water). Run down into beaker with main precipitate and boil to dissolve same. When the precipitate is well dissolved, filter off the free sulphur, and evaporate to white fumes with about 5 cc. 60% H_2SO_4 .

Then cool, dilute to about 60 cc.; neutralize with $\frac{1}{2}$ NH_3 (1 part strong NH_3 , 1 part H_2O) until there is a distinct smell of NH_3 . Note if white or yellowish precipitate separates out. If so, filter and treat it for bismuth.

To the solution add enough acetic acid to smell natural, and 5 grams of sodium acetate, dissolve same, and titrate for MoO_3 with standard solution of lead acetate, using tannic acid as outside indicator. If the titration should go beyond the point, titrate back with the standard ammonium molybdate used for lead titration. When the titration point is accurately reached, allow to stand 10 minutes, then filter out the lead molybdate, wash once with cold water. Make the filtrate distinctly acid, using 5 cc. strong H_2SO_4 , then precipitate the copper with H_2S . Wash and treat as above described for copper.

The reason why ammonium persulphate is added, and then destroyed, before the introduction of hydrogen sulphide is as follows:

The molybdic acid is evaporated with H_2SO_4 , especially in the presence of free sulphur; a small part of the molybdic acid is reduced to compounds of lower valency, some of which precipitate very slowly, and some not at all, with H_2S in acid solution. Hence the persulphate. Farther, when molybdenum occurs in solution as molybdic acid in the presence of ferric iron, and hydrogen sulphide is introduced, there are several reactions happening simultaneously. When the solution is hot, the H_2S acts rapidly on the ferric iron, reducing it to ferrous iron, which again acts on molybdic acid, reducing the latter to lower-valency compounds which are not acted on by hydrogen sulphide in acid solution.

On the other hand, when the solution is cold, molybdic trisulphide precipitates before this reducing action takes place, hence the solution must be cold while Mo is precipitated. However, a small amount of molybdic sulphide is soluble in water containing H_2S , probably as colloidal sulpho-molybdic acid. Hence the boiling before final filtration.

The titration with lead acetate is slightly interfered with, when copper is present, because copper gives a green color with the tannic acid indicator. The yellow color of molybdic acid with this indicator, however, comes out first, and after a little practice there is no diffi-

culty in seeing the end point, when the yellow changes to green. The titration is best done at ordinary temperatures.

When the lead-acetate solution is made up, enough ammonium acetate must be added to make sure that no basic lead salts will precipitate on diluting the solution to proper strength. To make up lead solution, dissolve 18.35 gm. lead acetate crystals, $\text{Pb}(\text{C}_2\text{O}_2\text{H}_3)_2 + 3(\text{H}_2\text{O})$, in 100 cc. strong solution of ammonium acetate, and make up to one litre.

Sometimes the molybdenum is not completely precipitated with hydrogen sulphide, even when the above precautions are carefully followed. In that case, it will always be recovered when the iron is precipitated, as follows:

Boil the filtrate from the H_2S precipitation with a few crystals of ammonium persulphate, to oxidize both the iron and molybdenum possibly still present in the solution, then add ammonia (dilute enough to prevent spluttering) until the iron and alumina are precipitated, and a distinct excess of ammonia is left in the solution. Boil a few minutes, still maintaining excess of ammonia, then filter, and wash with hot water. Dissolve the precipitate in dilute H_2SO_4 and determine the iron either by zinc and permanganate titration, or by bichromate titration.

The filtrate from the iron precipitation may contain a residue of molybdic acid; it is now boiled, to remove excess ammonia, then cooled, and made acid with about 5 cc. of 60% H_2SO_4 . Add H_2S for half an hour, then remove the H_2S tube, and boil the solution. If any molybdenum is left in the solution, it will now precipitate completely. Filter, wash with previously-boiled cold water. Add precipitate to the rest of the molybdenum, or titrate separately, as before.

The solution may now be treated for manganese, zinc, lime, and other substances, as described in the general method of analysis.

It will be noticed, that the above-described procedure would be interfered with by the presence of a large percentage of copper as compared to the molybdenum. Arsenic and phosphorus in appreciable quantities also would interfere, by the formation of compounds with molybdic acid.

None of the objections, however, are of any importance in practice, because they do not occur in any of the molybdenum ores that we have analyzed so far. To be sure, we have seen ores containing arsenic, where a little ammonium arseno-molybdate was formed. It was filtered off, dissolved in a little ammonia, made acid with sulphuric acid, reduced with zinc, and titrated with permanganate.

So thorough has been the sanitation of the Panama Canal zone that the last case of yellow fever contracted there was in 1905. This is the more remarkable as prior to the improvement of conditions on the Isthmus of Panama, not a year passed when Yellow Jack did not flourish among the native population, and travelers were frequently among the victims, where this terrible disease is endemic.

California's Volcano Still Active

Mount Lassen, contrary to the expectation of some, continues to give repeated though irregular evidences of temper. After an interval of rest, extending over several weeks, it suddenly went into action on the afternoon of December 10, discharging a large quantity of comminuted material and rocks that quickly converted the dazzling whiteness of the snow-clad mountain to an ominous, sombre dark gray. This eruption, it is stated, was accompanied by very little water vapor.

Thus far, Lassen has afforded an exhibition of three types of eruption, the Vulcanian, the Peléean, and the Strombolian. In the vulcanian type the explosions are violent, ejecting much consolidated ancient lava, accompanied by dense clouds of smoke (dust) and water-vapor. In the Peléean type, the volcanic cloud is so heavily laden with solid materials that it, together with the water-vapor, after rising rapidly above the vent, driven upward by the explosive force within the volcano, falls rapidly by gravity and rolls down the mountain side in heavy clouds, as on the morning of June 14, 1914. Strombolian eruptions consist chiefly of finely comminuted rock, small fragments and angular boulders, some of them large, torn from the sides of the vent, but there is little water-vapor present. The eruption of December 10, was evidently of this latter type.

The mud streams that are reported to have flowed from the crater some time since may be due to either of two causes: first, the rapid condensation of water-vapor, producing a large amount of water which would quickly wash down the accumulated fine material lying on the slopes of the mountain, forming rills of mud, which, uniting lower down, become good-sized streams heavily-laden with the ejected finer products of the volcano. Second, the welling-up in the crater of a large amount of the fine rock material saturated with water, the presence of which is due to condensation of water-vapor on approaching the surface. If this mud is ejected in sufficient amount, it would flow down the slope of the mountain in streams, the size of which would depend upon the quantity of material poured out and the velocity with which it is ejected. This phase is distinctly that characteristic of the Taal volcano, thirty miles south of Manila, on the island of Luzon, which went into violent eruption in 1912, after a long period of quiescence.

It is impossible to predict what Mount Lassen may yet do in the way of eruption. It may continue spasmodic eruptions, such as have characterized it during the past two and a half years, and finally settle down to a staid and uneventful existence, or it may at any moment break into violent and devastating eruption, destroying a good part of the mountain mass, and spreading a thick blanket of volcanic ash over hundreds of square miles of the surrounding country, as did Katmai on the Alaska Peninsula in 1912. Only time will tell; meanwhile, it is an excellent place for the curious to avoid, pending events at Mount Lassen.

Minerals Separation Decision

In the Minerals Separation decision rendered on December 11, the Supreme Court held that seven of the company's claims on patents were valid where the amount of oil used was in the proportion of a fraction of 1% to the amount of ore. Three claims which did not specify the precise proportion, but merely specified the use of "a little oil," were held invalid. The rejection of these claims is held by the company's representatives to be inconsequential, while the affirmation by the Court of the validity of the practicable patents held by it is said by them to be immensely valuable. The Supreme Court's decision reversed the findings of the Circuit Court of Appeals for the 9th circuit, and affirms the decision of the District Court of Montana as modified as to the three inconsequential claims.

The patents adjudged as belonging to Minerals Separation cover the so-called froth flotation method of concentrating copper and sulphide ores. The process involved the violent agitation of the powdered ore, mixed with water, and a critical proportion, a fraction of 1% per amount of ore, of oil or oleic acid. The result achieved is that the fine particles of valuable minerals rise to the surface of the mixture whence they are readily floated off into receptacles, while the valueless residue sinks.

The Court says: "The decision of the Circuit Court of Appeals will be reversed, and the decision of District Court modified to conform to the conclusions expressed in this opinion, will be affirmed."

The decision reviews at some length the arguments of both sides and then says:

"The evidence of infringement is clear. While we thus find in favor of the validity of the patent, we can't agree with the District Court in regarding it valid as to all of the claims in suit. As we have pointed out in this opinion there were many investigators at work in this field to which the process in suit relates when the patentees came into it and it was while engaged in study of prior kindred processes that their discovery was made. While the evidence in the case makes it clear that they discovered the final step which 'turned failure into success,' yet the investigation proceedings were so informing that this final step was not a long one and the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony, and in the claims of the patent as 'critical proportions' amounting to a fraction of 1% on the ore, and therefore the decree of this Court will be that the patent is valid, as to claims numbered 1, 2, 3, 5, 6, 7, and 12 and that the defendant infringed these claims, but that it is invalid as to claims 9, 10, and 11. Claims numbered 4, 8, and 13 were not considered in the decrees of the two lower courts and are not in issue in this proceeding." The Court points out that all allegations in the bill are denied and that the defendant (Hyde) "a man obviously experienced in the subject, says that in his opinion the whole basis for flotation concentration was disclosed in the Everson United States patent and the Froment British patent. It is clear that in the prior art as it is developed in this record, it was well known that oil and oily substances had a selective affinity or attraction for and would unite mechanically with the minute particles of metal and metallic compounds found in crushed or powdered ores but would not so unite with the quartz or rocky metallic material called gangue. It was also well known that the selective property of oils and oily substances was increased when applied to some ores by the addition of a small amount of acid to the ore and water used in process of concentration."

Prior to the patent in suit a number of patents had been granted, the decision points out, all of which, broadly speaking, consisted in mixing finely crushed or powdered ore with water and oil. From the resulting concentrate the metals were recovered in various ways. The Court adds that processes of this general character could be roughly divided into two classes. The process of the first class is called the "sur-

face flotation process," which depends for its usefulness on the oil used being sufficient to collect and hold in mechanical suspension the small particles of metal and by its buoyancy to carry them to the surface of the mixture. The other class, called "metal-sinking process," reverses the action of the surface flotation process. The process of the patent in suit, the Court says, consists in the use of the amount of oil which is "critical" and minute as compared with the amount used in prior processes, "amounting to a fraction of 1% on the ore." After describing this process the decision says "it is obvious that the process in suit is not of the metal-sinking class and while it may in terms be described as a surface flotation process, yet it differs so essentially from all processes in its character, in its simplicity of operation, and in the resulting concentrate, that we are persuaded that it constitutes patentable discovery."

Continuing, the Court says: "The prior processes which we have described required the use of so much oil that they were too expensive to be used on lean ores, to which they were intended to have their chief application, and the efforts of investigators for several years prior to the discovery of the process in suit had been directed to the search for a means or method of reducing the amount of oil used, and it is clear from the record that approach was being made, slowly, but more and more nearly to the result which was reached by the patentees of the process in suit in March 1905."

The Court characterizes the Froment Great Britain patent as "little more than a laboratory experiment" which has never proved of value in practice, while of the Kirby United States patent it says, "though approaching in some respects more nearly to the end attained by the process of the patent in suit, found its preferred application in the use of an amount of oil solution equal to one-fourth to three-fourths in weight of the ore treated, which was prohibitive in cost." It was at this point, says the Court, that patentees came into the field in investigation. They worked on the Cattermole process as a basis when they discovered that "an increase in the amount of froth reached its maximum when about 1% or slightly less on the ore of oleic acid was used," this froth of air bubbles held in suspension between 70% and 80% of the total mineral content of the mass treated. "It was promptly recognized by the patentees that this froth," says the decision, "was not due to liberation of gas in the mass treated but rather to the presence of air introduced in the mixture by the agitation which had been resorted to to mix the oil with the particles of crushed ore, which air, in bubbles, attached itself to the mineral particles, slightly coated as they were with what was necessarily an infinitesimal amount of oil, floated them to the surface." The lifting force, the Court says, is in the buoyancy of the air bubbles caused by agitation. It results without more discussion, says the Court, "that we fully agree with the decision of the House of Lords" in other cases.

The claim that the patentees of the patent are not the original discoverers of the process patented because an employee of theirs happened to make the analysis cannot be allowed. Equally untenable is the claim that the patent is invalid for the reason that the evidence shows that when different ores are treated preliminary tests must be made to determine the amount of oil and extent of agitation necessary in order to obtain best results.

COPPER output of Mt. Lyell, Tasmania, during the half-year ended September 30, 1916, was 7,104,520 lb., also 4183 oz. of gold and 170,399 oz. of silver. The cost of mining was \$2.50, smelting and concentration, \$2.76, and converting 38c., a total of \$5.64 per ton. In the previous quarter the cost was \$4.56 per ton. The blast-furnaces reduced 151,836 tons of ore and flotation concentrate.

SULPHUR production from the pyrite of Mt. Lyell has been proved practicable. Several kinds of muffle-furnaces are under trial.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

WAGES RAISED.—ORE TREATMENT AT ROBINSON.

Local mine-owners have again raised the wage-scale. Employees who have been receiving \$3.30 per shift, including miners, shovelers, trammers, and top-men, were given a raise of 20c., making \$3.50. Timber-men, machine-men, and other skilled workers who were receiving \$3.85 receive 15c. extra, making \$4. Hoist engine-men, mechanics, and skilled men who had been paid at the rate of \$4.40 get 10c., making \$4.50 per shift. This new increase makes a uniform raise of 50c. a shift over and above the wage-schedule in force in the district prior to the 10% increase made last April. The new rate will continue in force until further notice, according to the statement issued to the men by the different companies here. It is not based on any market quotations, and is in no way dependent on future conditions. The announcement that the operators had decided to raise wages came as a surprise. It was generally thought that no steps would be taken in the matter until after the State Industrial Commission had investigated the wage situation and made some recommendation. Members of the Commission did not put in an appearance, although it is reported that they were securing information on local conditions. The delay on the part of the Commission caused the operators to get together and carefully consider the wage question. They came to the conclusion that under the existing conditions an increase was justified, and quietly informed their employees of the new schedule when issuing pay-checks on December 5. The increase dates from the 1st of the month. Leadville is now a \$3.50 district for miners. All the large producers have instituted the new schedule, including the Iron Silver Mining Co., Western Mining Co., Empire Zinc Co., Leadville Unit of the U. S. S. R. & E., Star Consolidated Mining Co., Yak Mining & Milling Co., Down Town Mines Co., Julia Mining Co., Dinero Mining Co., Valley Mining Co., Louisville Mine, the Bowden Leases, and others.

The Progress Mining & Milling Co. has just completed a unit of the Wilson mill at Robinson having a capacity of from 150 to 200 tons, using a new process that had been tried previously and proved a success by William B. Brooks, assistant manager. The company was first organized about four years ago by Mr. Brooks and others, and until the early part of this year work was confined to laboratory tests at Leadville, on the lead-zinc ores of the Leadville and Robinson districts. The first plans of the company after fully proving the success of the process, included the taking over of the old American Zinc company's mill near the portal of the Yak tunnel. This deal was not closed, and the attention of the company was turned to the old Wilson mill at Robinson, situated in the centre of one of the largest and richest lead-zinc areas of the State. The manager, Ross D. McCausland, and assistant manager, W. B. Brooks, entered the Robinson district in March, and purchased the Wilson mill and mining property of 26 patented claims. The work of overhauling the old plant and installing new machinery was commenced at once. In spite of numerous delays in delivery of equipment, rapid and satisfactory progress was made. The plant is capable of treating from 150 to 200 tons per day. It is equipped with a 1000-ton crushing-plant, the largest set of Traylor rolls in the State, Denver Engineering Works' ball-mills, Dewey roasters, Wilfley, Burchart, and Deister tables, and a K. & K. flotation machine, the last being delivered at the plant a few days ago. The trial runs that have

been made since the installation of the flotation machine prove the value of the process. After being crushed the ore is reduced to 40-mesh in the tube-mills. Tables concentrate out the lead, silica being discharged in the tailing. The zinc-iron middling is roasted in the Dewey machines, then separated by flotation. The process recovers 80% of the zinc in a concentrate containing at least 40% metal. The greater part of the gold-content remains in the iron; the lead contains the silver. The process will yield these products: lead concentrate carrying some gold and silver, zinc concentrate, and a low-grade iron concentrate containing most of the gold. The zinc and lead will be marketed separately, and the iron will be stored to be cyanided in the coming spring, when a plant will be erected for this purpose. Results from the second days' run showed the galena from the tables to assay 75% lead, and only 1% zinc. The zinc concentrate from the flotation machine assayed from 40% to 46% metal, with a trace of lead. These results prove beyond any doubt the efficiency of the process for the separation of Robinson ore, and may be looked upon with considerable satisfaction.

The Progress company controls a great supply of ore. At present, there are 800 tons of crushed ore in the mill-bins, and 30 railroad carloads on the siding at the plant. The company owns the Wilson property, has a lease and bond on the Robinson, Felicia Grace, and Champion, and has contracted for the output of the Michigan, Colonel Sellers, and surrounding mines. Engineers who recently inspected these mines, and those who made reports on them in the past, place the minimum milling ore available as 3,000,000 tons, and the maximum at nearly double that figure. The average value of the ore as determined by numerous samples taken from every vein, streak, and face of ore now open is \$20 per ton; many of the samples assayed above \$50 per ton. No ore under \$15 will be purchased by the company under contract.

The Robinson district is credited with a production of \$36,000,000, the old Robinson mine alone contributing \$6,000,000. At the time of this output, nothing but ore that had a gross value of \$100 per ton, or better, was mined, with the result that much of the ore remaining is of fair value. With the present high prices for lead and silver it is possible that a large tonnage will be mined of sufficient value to be shipped direct to the smelters without separation. The Progress company also proposes to do some deep mining in its territory. All of the ore that has so far been discovered in the district has been found in what is known as the Robinson contact, lying between the white sandstone and blue lime. The ore in this contact has been developed to a depth of 1200 ft. in the Wilson mine, but no work has been done below it. Diamond-drill holes put down from the old Robinson tunnel several years ago cut a strong sulphide shoot at a depth of 212 ft. below the tunnel-level. The ore gave fair value in gold. The formations that have proved so productive in the Leadville district underlie the deepest workings in the Robinson area. These will be penetrated during the coming summer by several drill-holes to be put down from the lowest level of the Wilson mine.

Officers of the company are: Philip S. Smith, president; Ross D. McCausland, vice-president and manager; William B. Brooks, assistant manager; and M. E. Peters, secretary. The first three named, with R. W. McCausland and Martin Barber, form the board of directors. The main offices of the company are at 926 Equitable building, Denver.

JOPLIN, MISSOURI

A SURVEY OF THE MISSOURI-KANSAS-OKLAHOMA REGION.

Increasing zinc-ore prices during the past two months have brought this district out of its summer dullness to activity not exceeded heretofore, with the possible exception of June, 1915, when ore sold for \$137.50 per ton, basis of 60% metal-content. In September the average basis price of zinc concentrate was \$55.62; in October, \$65.56; and in November, \$86.25. As a result of these substantial advances, many properties that were shut-down during the summer have been started once more. The immediate prospect is unusual activity all winter.

The only serious trouble is the power question. Low water due to the drought, resulting in bad water, caused boiler trouble at the Empire District Electric Co.'s Riverton plant. Added to this, the company's three large turbo-generators have burned out, one after another, and during the past week the breaking-down of the last engine necessitated an order from the company prohibiting the use of electric current at the mines for anything except pumping. It is estimated that this means a curtailment of at least 20% of the district's production, some of the larger properties affected being the Picher mills at Picher, Oklahoma, the A. W. C. mines at Joplin, and the American Z. L. & S. Co.'s Klondike mill at Granby. These use electricity exclusively, and besides these there are many other smaller properties so equipped with motors. Many operators would use steam or gas, but they have no assurance of being able to get gas, and coal-dealers are refusing to supply new heavy consumers, declaring it is all they can do to take care of their present customers. In the meantime the power company is sparing no expense to get running once more, spending not less than \$300,000 in order to make certain that similar trouble will not occur again.

Notwithstanding the power shortage, the output of the district is greater than ever, the continued extraordinary developments in the Oklahoma field being principally responsible. During the past week the 'turn-in' from the Miami district was in excess of 2000 tons of blende, and there is every reason to believe that it will be close to this every week from now on, and may even exceed it. Most of the development is in the vicinity of Picher, Cardin, and Century, the new centres that have sprung-up, mushroom-like, in the past 18 months, on the level prairie $\frac{1}{2}$ miles north of Commerce. At Picher, the Eagle-Picher Lead Co.'s four mills are making regular turn-ins. The Netta, the last of these mills to be erected, is one of the largest in the district, having a capacity of 1200 tons in 24 hours.

At Century, the Montreal Mining Co. has just completed the construction of a new mill, and is regularly in the turn-in list. This property was the richest hand-jig mine ever opened here, and promises to be almost as much a record-breaker as a milling property.—The Lucky Kid also is operating regularly now, with large production.—The Welsh Mining Co. has just completed a new 400-ton concentrating plant that will add to the output. This company is backed by the Church-Mabon interests that developed the ground at this point. It was rich almost from the first drill-hole, but is expensive in pumping. The pumps now at work include a Pomona with a capacity of 4000 gal. per minute, a 10-in. Texas centrifugal pump, and a smaller Pomona, besides a number of air-lift pumps. It is asserted that the Church-Mabon interests have expended not less than \$50,000 for pumping alone.

At Cardin, the Blue Goose and Beaver mines continue to be heavy producers. A new company has taken hold of the Cornfield, and will start it during the coming week, working on a newly-discovered deposit of the north-east part of the lease.—Construction of two new mills has been started by the Commerce Mining & Royalty Co., owners of the Beaver and Blue Goose, one to be known as the Blue Jay. The U. S. Smelting Co. has just completed the re-construction of the old Ravens-

wood mill, which it moved from Reeds, Missouri, on a 60-acre lease not far from the Blue Goose.—The Walker Mining Co. has started working its new mill.—The Underwriters new mill is yielding concentrate at the rate of more than 100 tons per week.—The Admiralty Zinc Co. now has three mills operating.—Numerous other companies are at work, drilling or preparing to start new mills.

In the Webb City-Carterville district of Missouri, the most important addition to the producers is the Red Bird Mining Co.'s plant, owned by Tulsa, Oklahoma, parties already largely interested in this field, and situated on the site of the old En-

THE ZINC-LEAD DISTRICT OF OKLAHOMA.

deavor mine, just south of the American Z. L. & S. Co.'s group. This plant started a few weeks ago and is producing 60 tons of blende and a similar amount of lead each week, and yet is operating the mine and mill only one shift. This also excludes the sludge output, which averages $4\frac{1}{2}$ tons daily. The sludge-plant consists of 12 tables, with three more to be added this week, a Henry screen for sizing, and a 40-ft. Dorr thickener. The sludge-plant is operated by electric motor, but the remainder of the plant by steam, there being three 150-hp. forced-draught boilers, an innovation for this district. It is expected that the present output will be doubled when two shifts are employed, in the near future.

As previously mentioned, the output from Joplin has been greatly reduced during the past 6 weeks by shortage of water and electricity. The A. W. C. mines west of the city, with four motor-driven concentrating plants, have been able to operate only half-time, so far as power was concerned, and could not work even this much most of the time on account of the water. The company also had a surplus of 1000 tons of blende in its bins, and it is believed this had something to do with a several weeks' shut-down, which is now at an end. The blende, which the company willingly had sold at one time for \$75 per ton was sold a week ago at \$95 basis. The plants are in operation again.

At Duenweg the new plant of the Coahuila Mining Co. has been the biggest producer, and continues such. The company this week started up its No. 1 mill once more, after a shut-down since early in September; and also its No. 2 plant at Carthage, formerly the Hermosa.—At Duenweg the Evans-Hall-Soy mine, once known as the Rosebud, after a modest beginning following the completion of its new concentrating plant, has developed into a consistently heavy producer, with fine pros-

pects.—The Wampler interests have just got a shaft into ore on a lease south-west of the town, and hope to have a profitable mine in virgin ground. If they are successful it will mean the extension of the Duenweg field to the south-west a half-mile or more. The formation is similar to that found at the Baltic and Wilson mines.

Production at Granby, while handicapped so far as the largest plant was concerned, (the Klondike, which is electrically equipped), has been making big turn-ins during the past few weeks, particularly of silicate. To a large extent it is ore that was hand-cobbed during the summer, and held for higher prices.

On the whole, the immediate prospects for the Missouri-Kansas-Oklahoma region are very satisfactory. The large surplus of zinc concentrate that was on hand two months ago has not entirely disappeared, but so nearly that little is heard of it as a bearish tendency on the market. It is expected that the shortage in electric power will be entirely eliminated by the first of the year, and while cold weather will affect production somewhat, there is reason to believe that the year will end with the weekly output from the mines heavier than ever before in the history of the district.

PLATTEVILLE, WISCONSIN

SATISFACTORY CONDITIONS IN THE ZINC, LEAD, AND PYRITE BUSINESS DURING NOVEMBER.

Wisconsin zinc and lead miners enjoyed an unusually prosperous period during November. Remarkable advances were made in the prices of all mineral products offered for sale; weather conditions were ideal, allowing uninterrupted operations and perfect roads for teaming; tension in the labor demand, which was acute at the beginning of the month was lessened but not entirely relieved; and power furnished by the principal generating plants supplying the entire field was constant, and acknowledged to be fair by leading operators. With this combination of advantages it was surmised there would be a stimulated recovery of ore extracted, but it did nothing of the kind, and no deep search was required to ascertain the reason. As prices, especially for zinc ore, rose from day to day, miners prudently calculated that it would both pay to hold ore ready for shipment and conserve ore underground. In this they again proved their business acumen, and for a time while prices were soaring shipments of high-grade zinc ore from refining plants to smelter were significantly light. The beginning of November found blende in ordinary demand at \$70 per ton, base of 60% zinc-content. Medium and second grades held at \$5 per ton less, the range including ore assaying as low as 50% metal. Under this last figure all grades were designated as low, and many independent producers actually went begging for a market. This condition was of brief duration; immediately the spelter market displayed bullish tendencies, the price of zinc ore began to climb, and all grades of zinc ore were in active demand.

The reserve of ore in the field at the close of October, and conservatively estimated at 2000 tons, was soon eliminated, one quick deal for 1000 tons being closed in the Linden district, and the Eagle-Picher company cleaned-up the remainder in both the Midlin and Dodgeville districts. Toward the close of November there was almost a complete reversal of ideas on low-grade ore, which was being bid-in on a basis of \$1.20 per unit of zinc-content. Whereas at the beginning of the month some producers had been seeking a market, at the close a genuine scarcity of low-grade products to keep reduction plants running full time had manifested itself, and sharp competition developed among buyers to cover this class of ore offered in open market to the highest bidder. During this state of affairs the New Jersey Zinc Co. was exceedingly active, in numerous instances over-bidding its nearest competitor several dollars per ton; in this manner it managed to obtain

most of the low-grade ore offered, and shipments of high-grade refinery material from its separating plants at Mineral Point exceeded 6,000,000 lb. The Eagle-Picher Lead Co. was also active in its quest for high-grade zinc ore, and secured a fair quantity. The Grasselli Chemical Co. of Cleveland, Ohio, became the runner-up for the field on buying, following closely on the heels of the New Jersey Zinc Co., and through contract arrangements cutting-in on several of the old-established buying-agents here. The Wisconsin Roasters and the National Separators treated large quantities of low-grade ore, and shipments of finished product became heavier toward the end of the month.

The close of November found miners exceedingly affluent, and in good humor for Thanksgiving Day. Zinc ore had reached the \$100 mark for premium grades, and the base held strong at \$98 per ton for 60% blende. All other grades were in good demand, and producers displayed a uniform tendency to withhold shipments. Whether this followed a concerted agreement or otherwise is not known, but the situation was quite apparent to the close observer.

In other ways November contributed material gains to a still higher stage in physical development of the local field. Newly-developed mines, with complete modern equipment, were introduced for the first time in the Linden, Midlin, Platteville, Benton, and New Diggings districts. Official announcement was made by the Wisconsin Zinc Co. that early in 1917, three new power and mining plants would be constructed in the Benton district. A mill was being built at the Champion mine at New Diggings during November, the purpose of which is to wash out all lime compounds from the finished refinery ore, a contamination for which refiners are at present suffering severe penalties. Several classifiers and eight slime-tables were being installed. In addition to the improvement made by the building of the wet mill a great warehouse was being erected where supplies of all kinds for the mines, mills, refineries, and boarding-houses of the Wisconsin Zinc Co. will be stored. Drilling operations continued effectively in the southern districts, and several new mining companies were organized.

Proportionate gains were registered in the price of lead ore, zinc carbonate ore—of which a small quantity was marketed during November, and iron pyrite. Lead ore was in fair demand at the beginning of the month on a basis of \$80 per ton, the price advancing steadily until \$91 had been reached. Even with this inducement at hand a small tonnage cleared, producers scenting higher prices and withholding shipments.

Carbonate ore, quotations for which are governed by calamine quotations of the Joplin field, Missouri, made substantial advances, going from \$40 to \$65 per ton, basis of 40% zinc-content. Wisconsin miners were at the mercy of such buying as was offered by outside interests, fair-grade ore selling on a basis of \$30 per ton, at which price a small tonnage cleared, the bulk of the ore held being carried over.

Iron pyrite that has been coming from the reduction plants exclusively, and mainly under contract arrangement, showed increases in price, the average being \$4 to \$5 per ton at the beginning of the month. Offers of \$10 per ton were revealed in certain quarters, but shippers tied-up under contract failed to share in the improved prices. Crude iron pyrite, in the hands of independent producers, was not to be had, as mines capable of producing in quantity had long been abandoned because of the unsatisfactory state of the market all the year, so there was no one so situated in this respect that might take advantage of the increase in price. An attempt to raise crude pyrite was being made to meet the better market.

Deliveries of ore from the 1st to 25th were 44,376,000 lb. zinc, 722,000 lb. lead, and 5,586,000 lb. of pyrite. The gross recovery of crude ore totaled 37,000,000 lb.; net refinery ore to smelter direct and mine run under contract to Grasselli Chemical Co. 24,000,000 lb. There was 2000 tons of reserve ore in the field, all grades, at the end of the month.

SUTTER CREEK, CALIFORNIA

OLD EUREKA, KEYSTONE, CENTRAL EUREKA, AND SOUTH EUREKA.

The shaft at the Old Eureka mine has been unwatered and re-timbered to a depth of 1150 ft. from the surface. The shaft appears to be in good condition as the water recedes, and no caves have been encountered since passing the 800-ft. station. With the exception of a few charred timbers found near 500 ft., no evidence has so far been found of the fire that is said to have caused the closing of the property years ago, so the damage done by that fire must have been confined to other shafts of the property. Men are engaged this week installing the new engine, and in building up around the collar of the shaft to bring it to the level of the new hoist. The construction of a large change-house for the miners will be commenced as soon as the necessary lumber arrives.

The heavy rain here during the early part of last week caused a small landslide on the hillside behind the new hoist building in course of construction at the Old Eureka mine, and some damage was done to the foundations being laid there for machinery. A small retaining wall will prevent trouble of this kind in the future. The shaft has been unwatered to a point just below the 1200-ft. station, and good headway is also being made in raising and filling in around the shaft-collar.

The Old Eureka shaft has now been cleared and re-timbered to a depth of 1225 ft., some delay having been caused by catching up a small cave at the 800-ft. station and in handling increased water. From 50,000 to 60,000 ft. of square timbers monthly is being used in the shaft. The dirt road leading from the county highway across the gulch to the mine is being reinforced with broken greenstone, several men and teams being engaged at this improvement. John R. Cahill of San Francisco has the contract for the erection of the new head-frame and ore-bins. This structure is gradually taking shape, as the immense timbers are being bolted into place above the 36-ft. concrete piers. Two of the hoist-drums have been put into place in the new engine-room built east of the shaft, and foundations for the engine are ready, so that the engine could be ready for operation within a few days were it not for the delay in arrival of electric equipment. Factories are so far behind with their orders that motors ordered last February for this plant have not yet been delivered, and it seems likely that there will be still further delay. The new hoist will have a lifting capacity of 15,000 lb. from a depth of 3300 ft., 1200 ft. below the present bottom of the mine. The Old Eureka hoisting plant is of similar construction to that recently installed at the Plymouth Consolidated Mines, although the latter is designed for a 5000-ft. haul.

The Keystone mine is to resume regular mining operations about the 15th of this month, by which time the shaft repair-work started during the strike will be completed. The shaft has been re-timbered to a point 400 ft. from the surface with timbers 18 by 18 in., and 18 ft. in length. The shaft-stations have also been enlarged and improved, concrete floors having been laid and modern appliances installed for handling supplies and ore. The company is also paying particular attention to sanitation and taking every possible precaution to safeguard the lives of its employees. C. R. Downs of Sutter Creek is superintendent, and B. I. Hoxsie is the foreman.

After two weeks' hauling by means of a large truck, all the machinery, buildings, and equipment of every description have been transferred from the Amador Queen mine south of Jackson to the North Star shaft of the South Keystone group. All possible speed is being made in getting the plant installed at its new site. Owing to the small amount of water in this shaft, only a short time need elapse before driving and cross-cutting can be started at the 600-ft. level to prospect the several claims of this consolidation. John A. McIntire of Sacramento, who is largely interested in this property, was a Sutter Creek visitor last week.

A cross-cut driven 640 ft. west from the 1800-ft. station of the Central Eureka mine has cut some good-looking quartz within the past few days. While low grade at the point of intersection, drifts will be run north and south on the vein, which appears strong and of good width. In the hope of insuring more rapid progress in sinking the shaft, the management contemplates having the men do the work on contract. The progress made since sinking commenced has not been up to expectations so far, and it is imperative that the shaft be sunk and new levels opened with the least expense, as the mine is being operated on assessments. The vein just encountered in the west ground is an encouraging feature, for it was in cross-cutting to the west in the adjoining South Eureka ground that the rich orebodies were developed several years ago, just in time to save that mine from closing down after a long period of assessments. The president, V. S. Walsh, and J. Toplitz, one of the directors, visited the property during the past week. Fred Jost is superintendent and W. J. Bryant foreman.

Contracts have been let for sinking the Central Eureka shaft at the rate of \$21 per foot, the company furnishing engineers, all tools, and supplies, except powder. Better progress has been made during the past week, the shaft having reached a point about 100 ft. below the 3200-ft. level. It is expected that sufficient ore will be developed by opening two new levels below 3200 ft. to keep the mine in successful operation for many years.

An encouraging development was made at the Oneida mine, part of the South Eureka company's holdings, during the week, a lode of good milling grade, varying in width from 5 to 15 ft., having been opened for a length of 109 ft. on the 2600-ft. level. The orebody so far gives every indication of persistence, and its discovery at this depth is particularly pleasing in view of the fact that the ore heretofore encountered in the lower levels of this mine has proved of low value. The Oneida was at one time equipped with a 60-stamp mill, and the grade of ore mined in the upper levels gave promise of a great future for the property, but the lower-grade material found at depth discouraged the owners, who ceased operations, disposed of their milling equipment, and finally sold their holdings to the South Eureka company. A cross-cut was driven on the 1800-ft. level to connect the two shafts, and for a long time the shaft below this connection was not unwatered. Sufficient ore was mined above 1500 ft. to keep 20 stamps in operation for a few months prior to the strike, but if this recent discovery proves as valuable as expected, the mill capacity will doubtless shortly be increased.

The orebody discovered recently on the lowest level of the Oneida mine is widening as work progresses, and still retains its value. For the first 100 ft. or so of driving the vein varied in width from 5 to 15 ft.; it has now been driven on for about 200 ft. and measures 30 ft. across the face. The old ore-bin at the shaft-collar has been repaired, and a new bin and waste chutes are now in course of construction. Twenty stamps are dropping constantly.

L. R. Poundstone of Colusa was a Sutter Creek visitor last week on business connected with the Rose mine, which is east of Sutter Creek. An engineer and pump-man are keeping the main shaft on the hill unwatered, and it is understood that negotiations are pending for a change of ownership and a resumption of operations. The present plant consists of a 20-stamp mill, small hoist, and compressor; and there are two shafts in good condition.

A few men are employed unwatering and repairing the Hardenburg shaft near the Mokelumne river, south of Jackson. The mine has been idle for three years and the condition of the shaft is such that only a few men can be worked to advantage at present; but a new pumping plant is being installed, which will result in better progress. Other improvements are being made, the surface plant receiving a thorough overhauling.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU. The November yield of the Alaska Gastineau was 167,600 tons of ore assaying \$1.13 per ton. Compared with October there was an increase of 9600 tons, but a decrease of 19c. per ton in value. The recovery was 81.71%.

The suit of the Ebner v. the Alaska-Juneau company concerning water-rights on Gold creek is still before the Court at San Francisco, and a decision will not be given until next May.

Appropriations submitted to Congress include \$100,000 for

AT THE ALASKA GASTINEAU PROPERTY, JUNEAU.

a bridge across Gastineau channel from Juneau to Douglas island.

ARIZONA

GLOBE. A large deposit of high-grade manganese is being developed east of the Big Johnnie claims of the Old Dominion company, and adjoining the Iron Cap mine. Wright & Buckingham are lessees. Thirteen carloads have been sent to Chicago. A company has been formed to extend operations.

On the 800-ft. level of the Iron Cap mine the Arizona Commercial vein was cut last week showing 5 ft. of hornite.

MAYER. This district of Yavapai county is reported to be very busy. There are 250 men at the Blue Bell, 150 at the Stoddard, 150 at the Henrietta, 100 at the De Soto, and 100 at the Butternut. The new 100-ton smelter of the Great Western Smelting Co. was blown-in last week. The Big Lodge and other mines will supply the ore. The plant was partly made from material at the old United Verde smelter at Jerome. A. C. Cole is superintendent.

MIAMI. The Greater Miami Copper Co.'s manager, H. C. Malloy, has made a report on the property. Two large fissures have been opened considerably by shallow shafts and adits. From one vein a good deal of ore has been mined and treated locally in a crude way. Later development opened high-grade copper-gold-silver ore. Some rich silver ore is to be sent to the Selby smelter. No. 2 adit, started on ore containing 35 to 12% zinc, opened sulphides at a depth of 75 ft., the zinc disappearing, copper ore taking its place. So far the adit is in 84 ft. in similar material. A road 2 miles is to be constructed, costing \$1000. A mill is proposed.

CALIFORNIA

GEORGETOWN. The old Woodside mine is to be unwatered by R. H. Shannon.

OROVILLE. In the Banner mine operated by Richard Phillips ore assaying \$25 per ton has been opened on the 400-ft. level. The vein is 4 ft. wide and is getting wider. Twenty-five men are employed. Ten stamps are to start crushing. A transmission-line four miles long is being erected.

REDDING. Effective from December 1, employees (200) of the Balaklala Copper Co. at Coram will receive an increase of 25c. per shift; at Kennett the Mammoth Copper Co. is to pay its 1100 men a similar advance; and at Keswick the Mountain Copper Co. will do likewise to its 600 employees. The lowest wage in the copper belt is \$3.25 per day.

SONORA. Diamond-drilling, and exploration at 1300 and 1800 ft. constitutes some of the work being done at the Black Oak mine.

TAYLORSVILLE. Labor troubles are reported from the Engels copper mine in Lights canyon, caused, it is alleged, by I. W. W. agitators. Demanding an increase of wages from \$4 to \$5 per day, 200 men walked out, after which the company closed the property, putting 400 out of work. There was some fighting, but this was quelled by the Sheriff. The strikers said that men at the Walker copper mine, near Colfax, were getting \$5 per shift.

COLORADO

BOULDER. A new 150-ton tungsten mill, using tables and oil flotation apparatus, was started by the Gold Hill Concentrating Co. on the Slide dump last week. The plant is backed by G. W. Teal, C. A. Barr, R. R. Kermack, and C. Gustafson.

CRIPPLE CREEK. An extra dividend of 2c. a share was paid by the Portland on December 18. This equals \$60,000, and makes \$420,000 for 1916.

Eighty tons of ore from the Shoo Fly mine on Womack hill was valued at \$4000.

The Carolina company has taken over the Ajax mine. The three-compartment shaft is to be deepened from 1450 ft. to water-level, probably between 1300 and 2000 ft. The upper levels are to be explored.

The properties of the Granite Gold Mining Co. on Battle mountain are producing more than 100 tons per day of better than average grade ore. Development on company account is confined chiefly to the 1400 and 1600-ft. levels of the Dillon shaft.

A new company, the Modoc Consolidated Mines Co., has recently been formed to operate the Modoc mine situated in the saddle between Battle mountain and Bull hill. Among other proposed work the company intends to sink a vertical shaft to a depth of 1500 ft. to replace the old inclined shaft. The Modoc mine adjoins the Portland estate, and so far has produced \$2,000,000. A. H. Frankenberg of Pueblo is general manager.

It is expected that work will be resumed in the heading of the Roosevelt drainage-tunnel about December 10. Re-timbering of the Elkton shaft from the surface to the 200-ft. level necessitated a cessation of work in the tunnel. The heading was advanced 295 ft. during 17 days of November on which work was in progress, and is now 2100 ft. east of the Elkton shaft. At the last time measurements were taken the flow of water from the portal was 9500 gal. per minute.

On December 10, the Cresson Consolidated paid a 25% dividend; in addition to the regular monthly dividend of 10%, an extra dividend of 15% was distributed. It is reported that the extra payment will be made from the returns on three carloads of ore netting over \$60,000 per car. At a recent meeting of the newly-elected directors of the company, A. E. Carlton was re-elected president.

TELLURIDE. During November the Tomboy company treated 12,000 tons of ore yielding \$96,500. The profit was \$28,500.

IDAHO

According to Robert N. Bell, State inspector of mines, the lead and silver output of Idaho this year will about equal that of 1915, but the selling value is much higher. Zinc production will be much greater. The dividend total will exceed any previous year.

GILMORE. The Pittsburg-Idaho company paid 6c. per share on the 8th. This makes \$100,000 for the year. The reserve fund is \$100,000; and all debts have been paid. The mine is in good condition, and 190 men are employed.

KELLOGG. To supply its new smelter with limestone the Bunker Hill & Sullivan company has leased the old Evolution mine near Osburn. The rock contains a little lead, zinc, copper, silver, and gold, and 37.5% CaO. The owner of the property is to receive payment for 25% of the metal-content of the rock. The mine has an interesting history, being the first quartz location in the Coeur d'Alene.

PINE CREEK DISTRICT. The Kellogg United Mines Co., capitalized for 2,000,000 shares at 25c. each, has been organized by Spokane and Coeur d'Alene men to take over and operate three groups of claims in this district. The incorporators are Samuel A. McCoy, J. A. McEachran, George H. Wilson, and G. W. Sommer, all of Spokane, and Theodore Brown of Kellogg.

MICHIGAN

HOUGHTON. On January 1 about 17,000 men will participate in the bonus distribution of 25c. for each day for every employee who worked steadily from July 1 to December 31. There are now 25,000 men employed at the copper mines.

MISSOURI

JEFFERSON CITY. During the year ended June 30, 1916, two plants in Newton county produced 6300 tons of tripoli worth \$65,767. This is used as an abrasive and for filtering.

JOPLIN. The electric-power situation was improved last week by the Empire District company starting a 19,000-hp. turbo-generator. This will supply 60% of the district's normal demand, and will suffice underground work on day and mills on night shift. A number of mines thereby resumed work. A new 17,000-hp. generator is expected to arrive at an early date from the General Electric Company.

Ore prices were \$5 per ton weaker last week, due to a lower spelter market. The output of the Missouri-Kansas-Oklahoma region was 10,132 tons of blende, 293 tons of calamine, and 1250 tons of lead, averaging \$94, \$54, and \$91 per ton, respectively. The total value was \$1,071,434, and \$32,515,132 for 49 weeks.

MONTANA

BUTTE. During November Butte & Superior produced 14,300 tons of concentrate assaying 53% zinc from 53,880 tons of ore. The recovery was 93.7%.

To arrange for a spur-line for the eastern part of the district the Tuolumne and Bullwhacker companies have conferred with the Great Northern Railroad.

The Butte-Detroit company has started the Ophir concentrator on zinc ore from the Davis-Daly. The present capacity is from 150 to 200 tons per day, which is to be increased. This is the third zinc mill at Butte, including the Butte & Superior and Ehn Orlu.

ELKHORN. The East Butte Mining Co. should have its mill running early in 1917. Its capacity is 300 tons per day. The main shaft is being sunk another 100 ft.—The Rothfuss & Dickman mill is operating with good results.—The Elkhorn Queen is shipping regularly, and has a large quantity of ore available.

MARYSVILLE. During November the Barnes-King Development Co.'s bullion yield was \$80,024 from 7531 tons of ore. The Shannon mine contributed 3093 tons of \$15.80 ore.

NEVADA

ELY. Another 500-ton unit is to be erected at the Giroux mill of the Consolidated Copper Mines Co. The first unit is expected to start work early in January.

GOLDFIELD. At a depth of 840 ft., and 800 ft. north of the main station, the Reorganized Kewanas has opened \$45 to \$67 ore. Work is conducted through the Laguna shaft of the Goldfield Consolidated.

GOOSESPRINGS. The Contact, Copper Metal, and New Dominion groups of claims have been acquired by C. B. Stewart and others of Salt Lake City.

A shipment of copper-platinum ore from the Boss mine has just been treated at the Garfield smelter. The last carload was settled for \$6000.

LUNING. This district is as active as ever, producing between 2000 and 3000 tons of ore monthly. Most of the ore is a carbonate. The deepest shaft is 450 feet.

PICQUE. Results at the Consolidated Nevada-Utah mill are better than expected, the capacity being 10% greater. The ore treated contains zinc and silver. The heating system is a success. A heavy flow of water was encountered on No. 14 level.

THOMPSON. When the Mason Valley company resumes smelting here, it will have a large supply of ore at its own mine, and at the Bluestone mine in charge of C. D. Kaeding.

UTAH

Dividends paid by Utah companies during 1916 are as follows, according to the *Herald-Republican* of Salt Lake City:

	Per share	Amount	To date
Cardiff	\$0.75	\$ 375,000	\$ 500,000
Centennial-Eureka	1.00	100,000	4,000,000
Chief Consolidated	0.20	176,000	527,000
Eagle & Blue Bell	0.05	45,000	492,600
Eureka Hill	1.00	10,000	10,000
Gemini	16.00	80,000	2,435,000
Grand Central	0.04	20,000	1,634,750
Iron Blossom	0.35	350,000	2,850,000
Horn Silver	0.05	20,000	5,662,000
Judge Smelting	1.00	135,000	1,590,000
Lakeview Mining	0.10	65,000	124,000
May Day	0.07	56,000	300,000
Mammoth	0.25	100,000	2,420,000
Pacific Gold	0.02	8,000	8,000
Silver King Coalition	0.60	750,000	14,705,000
Silver King Con.	0.45	286,875	1,229,240
South Hecla	0.15	39,525	39,525
Utah Consolidated	3.75	1,125,000	11,434,000
Utah Apex	0.75	396,150	521,200
Utah Metal & Tunnel ..	0.50	342,470	1,243,470
Utah Copper	12.00	19,494,110	52,161,110
Total		\$24,374,430	\$103,886,895

The total in 1915 was \$10,025,000. Most of the increase was due to the Utah Copper Co., which paid under \$7,000,000 in 1915.

BINGHAM. The flotation plant at the Utah Metal company's mill is to be enlarged, giving a daily capacity of 300 tons, an increase of 75 tons.

The Utah Copper Co. of Utah has taken over the Ohio Copper Mining Co., paying all debts and liabilities of the latter company, which were over \$1,500,000.

GARFIELD. In the Arthur mill of the Utah Copper Co. improvements are under way in the fine-grinding department. More concentrators will be needed to care for this material. The company has 6000 acres for impounding tailing, around which a levee is to be built as it fills.

TINTIC. On December 9 the Gemini company paid \$6 per share, equal to \$30,000. This year's total is \$80,000, and \$2,435,000 to date.

The Tintic Milling Co.'s plant is treating 200 tons daily.

Two shifts at the Utah Ore Sampling Co.'s plant are passing through 600 tons of ore per day.

At the Tintic milling plant the seven roasting-furnaces are treating 200 tons of ore daily. The extraction is highly satisfactory.

On the 28th the Eagle & Blue Bell pays 5c. per share, equal to \$45,000. The total for this year is \$90,000.

The Grand Central pays 4c. on the 23rd, equal to \$20,000.

It is considered that Utah lake, 15 miles from Tintic, is the source of the water trouble in Tintic mines, and its drainage is now being discussed. At a depth of 2018 ft. the Eagle & Blue Bell mine cut a large flow of water, suspending sinking operations. At 1790 ft. the Chief Consolidated encountered water, and at 2310 ft. the Grand Central.

CANADA

BRITISH COLUMBIA

SILVERTON. Dividends are to be paid quarterly, instead of monthly, by the Standard Silver-Lead company. A loss of \$1111 was made in October, against a profit of \$17,785 in September, \$137,637 in March, \$88,008 in April, and \$40,968 in May. No zinc concentrate was shipped in October, but 3000 tons worth \$39 per ton net are now on the way to smelters. The surplus is \$202,669.

ONTARIO

COBALT. From the treatment of 162 tons of high and 6462 tons of low-grade ores, the Nipissing produced silver valued at \$246,630. The refinery shipped 490,782 oz. of bullion, partly from custom treatment. Development on No. 490 vein was satisfactory during November.

PORCUPINE. Gold production of the Dome Mines Co. in November was \$177,000 from 37,500 tons of ore. The cost was \$2.88 per ton.

KOREA

The Seoul Mining Co., operating the Suan concession in Whanghai province, Chosen, reports the following results for November: total recovery, \$141,750. In the Tul Mi Chung mine, developments in several workings are very promising. A favorable showing was made in several of the prospects being developed, the most important being an orebody 10 ft. wide, averaging \$9.50 gold per ton.

During October the Oriental Consolidated produced bullion worth \$123,836 from 26,391 tons of ore. The September rainfall was low, and this season's rain will not fill the Chorrre reservoir. Okura & Co. is to supply power at 1.5c. per kw.-hr., a reduction of a half cent. Cholera has killed hundreds of people in Japan, and the disease entered Korea late in September, but there have been no serious cases north of Seoul and Chemulpo.

THE STATE SCHOOL OF MINES, University of Utah, at Salt Lake City, is to have a course for prospectors from January 8 to February 3, 1917. Robert S. Lewis, of the department of mining, says that the work is in the nature of an experiment, and changes will be made to suit the needs of those who register for the course, should there be a real demand for such instruction. The subjects include geology and mineralogy, mining and milling, metallurgy, and laboratory work. There are no fees, save \$1 for registration.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

J. R. FINLAY has returned to New York from Arizona.

J. W. BRYANT is serving with the Royal Engineers in France.

R. H. CHANNING was here last week, on his way from Los Angeles to New York.

K. C. LI passed through San Francisco on his way from Shanghai to New York.

L. A. SMITH has been appointed inspector of mines for the Federated Malay States.

CHESTER F. LEE, of Seattle, has been examining mines in Butte county, California.

HERBERT W. GEPP, manager for the Amalgamated Zinc Co., has returned to Broken Hill.

C. H. BANKS has recovered from wounds received while with the Tunneling Corps in France.

D. D. HOMER, assistant general manager of Butters Divisadero, San Salvador, is in San Francisco.

W. S. BLACK has been appointed manager of the Ajax mine, at Cripple Creek, for the Carolina company.

E. H. C. OLIPHANT, editor of the *Australian Mining Standard*, returned to Australia by the *Sierra* on December 19.

A. S. WHEELER has resigned as inspector general of mines for the Chinese government and is on his way back to London.

W. J. C. SCRUTTON has resigned the position as manager for the South American Copper Syndicate in Venezuela, owing to ill-health.

J. B. TYRRELL is in the East Kootenay district, British Columbia, examining and sampling the Paradise mine, west of Invermere.

E. L. FORBES, local secretary of Butters Salvador Mines, has arrived in San Francisco from the mines in Salvador, and will spend the winter at Los Angeles.

BEN B. LAWRENCE made a visit of inspection to the Cornucopia mines of the Baker Mines Co., in Oregon, on his return from San Francisco to New York.

GEORGE H. GARREY, consulting geologist in charge of exploration work for the Tonopah Belmont Development Co., was at Salt Lake City this week, on his way to south-western Colorado.

H. C. BELLINGER has been appointed general manager of the Chuquicamata mine, for the Chile Exploration Co., in succession to FREDERICK HELLMAN, who is now chief consulting mining engineer to the Guggenheims.

A. H. COLLEMAN, general manager for the Seoul Mining Co., has resigned the active management of its Korean properties, and will devote his time to personal mining interests in the Orient and the United States. He continues his connection with the Seoul company as a director, so that the company will still have the benefit of his knowledge of the mines, which were developed during the past eight years under his organization and management from mere prospects into one of the best paying properties in the Far East.

The International Committee of YOUNG MEN'S CHRISTIAN ASSOCIATIONS, whose North-west headquarters are at Portland, Oregon, has just concluded a financial campaign at Butte for \$200,000 for a miners' Y. M. C. A. building. Among the large personal givers were C. W. Goodale, \$5000; T. F. Cole, \$2000 by telegram from Jerome, Arizona; also \$350 each from D. C. Jackling and N. B. McKelvie of the Butte & Superior; East Butte Mining Co., \$5000; John Gillie, \$500; and L. O. Evans, attorney for the Anaconda company, \$1000. The total subscriptions were \$202,475.

THE METAL MARKET

METAL PRICES

San Francisco, December 19.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	35
Pig lead, cents per pound.....	7.75-8.75
Platinum, soft and hard metal, per ounce.....	\$85-91
Quicksilver, per flask of 75 lb.....	\$80
Spelter, cents per pound.....	13
Tin, cents per pound.....	43
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, December 19.

Antimony, 50% metal, per unit.....	\$1.00
Chrome, 40% and over, f.o.b. cars California, per ton.....	15.00
Magnetite, crude, per ton.....	6.50-9.00
Manganese, 50% (under 35% metal not desired).....	16.00
Tungsten, 60% WO ₃ , per unit.....	20.00

Advice from New York states that Great Britain has bought tungsten ore in Bolivia and the Argentine at \$18 per unit for the first quarter of 1917.

New York, December 16.

Antimony: No business is reported, and the nominal quotation is unchanged at \$1.50 per unit.

Molybdenite: A dealer asserts that an effort to corner the market has been partly successful. For 90% concentrate the quotation is \$1.75, but it is nominal for the reason that there is so little to be had.

Tungsten: One of the larger producers announces an advance to \$20 per unit, following heavy sales for both prompt and forward metal is lower; lead dull and easy; spelter is unsettled and dull.

EASTERN METAL MARKET

(By wire from New York.)

December 19.—Copper prices are upset by peace talk, re-sale metal is lower; lead is dull and easy; spelter is unsettled and dull.

COPPER

Prices of electrolytic in New York, in cents per pound.

Continued strength characterizes the silver market, an upward tendency being apparent, the occasional recession indicating nothing unusual. Writing on November 23, Samuel Montagu & Co. of London say: "Enquiry is not confined to mintage alone, but embraces orders for general purposes, British and Continental, and also for the Indian Bazaars. The unfavorable views taken in India have caused a bear position to be opened in the London market—a state of affairs, in view of the statistical position, not without danger. It cannot be

challenged that the present condition of the market is more sound than when the spectacular movements in May last carried the quotation to 76.87c. During the intervening period the Chinese stock has been greatly reduced, America has been relieved of certain accumulations she then held, and the Indian currency figures, notwithstanding large continuous purchases for the Indian mints, show a declining tendency. The silver market has often lived up to its reputation of doing the unexpected, but the situation is such that further advances may be expected before the close of the year, provided no new factor intervenes."

Tin is quiet at 42.50 cents.

ANTIMONY

On the whole, the New York market is quiet but firm, with quotations ranging from 14 to 14.50c. It has been reported from time to time that munitions makers are likely to buy, but so far their business has not materialized. It is said by one authority that considerable effort is being made to obtain antimony free from the British restrictions, but without much success. Asiatic grades, of course, are subject to agreement that they will not reach the hands of Britain's enemies, just as tin and ferro-manganese are, and the would-be buyers are willing to pay 1/2c. higher to be free of the restriction.

Eastern Metal Market

New York, December 17.

The metals have been rendered quieter by the German peace scheme. Although Germany's proposal may not be accepted, and the general feeling is that it will not be, her announcement will drive home to consumers a realization that the War may be ended sooner than was expected, with the result that buyers are likely to become even more conservative than they have been. Should the War end suddenly it will have a profound effect on all metals. It is needless to emphasize the extent to which the direct and indirect demand has sprung from the ammunition makers. Another important development is Great Britain's further efforts to conserve her supply of copper. She has prohibited the use of the metal except for Government work, as well as forbidden all trading except under special permit. American copper prices are so far not affected, which demonstrates the strong position of the metal, and the solid way in which the producers are booked up for months to come.

Zinc has declined in a quiet market. It seems to have been more affected by the peace proposal than the other metals.

The scarcity of lead continues. Some talk is heard of manipulation being partly responsible for the scant supply.

Tin is dull and lower.

Antimony is firm, but quiet.

The high prices for pig iron, which range from \$30 to \$35 per ton at furnace, has caused buying to slow-up. For steel products, especially shipplates, the demand is as strong as ever, with both domestic and foreign shipbuilders clamoring for material. At the close of November the unfilled tonnage of the United States Steel Corporation was 11,058,542 tons, an increase of 1,043,282 tons as compared with October 31. Orders for nearly 500,000 tons of rails have been placed by the railroads for 1918 delivery, and the Pennsylvania Railroad is expected to place orders at an early date for 205,000 tons for delivery in that year.

A bad feature of the situation is the growth of railroad embargoes against material for export originating in the Middle West. They are trying to avoid the congestion of port terminals which so paralyzed traffic last winter. Of course, in one sense, the embargoes will have a salutary effect, otherwise they would not be declared. The embargo on various points in New England was raised December 10. Metals can be shipped and delivered to the brass mills in that district, but care must be taken not to ship in excess of needs, otherwise the embargo will be lowered again.

COPPER

Despite events of world-wide importance, which theoretically, at least, would seem to entail a depression in the copper market, prices are as firm as ever, if not a little stronger. The truth is that the metal is so thoroughly entrenched that sentiment cannot easily do it harm. The market has been quiet, and it was made more so by the announcement of Germany's peace proposal, but prices remained firm. Then, on Monday came news from London that Great Britain had forbidden all transactions in copper except under special license. All holders of the metal were ordered to furnish the Government with the details of their stocks and quantities due on contracts, with the further and more important stipulation that the use of copper was prohibited except for Government work. These strict regulations were designed, as were those of early in the year forbidding trading in futures, to conserve Great Britain's supply of the metal for war purposes, and also to prevent speculation which threatened to make the Government exorbitant prices for a necessity of war. Electrolytic dropped £3 in London (to £168) on the day of the announcement, but the Ameri-

can market did not change. The strength of the market lies in the fact that the entire production for the first quarter of 1917 is sold, and that fully 80% of the production in the second quarter is under contract. January copper is held at \$5.50c.; first quarter at 35c., second at 33.50 to 34c., third at 32.50 to 33c., and fourth at 31.50 to 32c. First quarter has been quoted at 36c. and upward. It is considered not unlikely that any of these prices might be shaded as a result of private negotiations. One who wants to sell copper has to search for a buyer who wants the metal, and a buyer has to search for a seller who has the metal, and the scarcity makes the latter not an easy proposition. The brass business is as heavy as at any time. Sheet brass is sold-up for the second quarter, except for odd lots. The American mills prefer to make sheets 10 to 12 in. wide which export buyers are taking, although abroad they really want sheets 20 in. and upward in width. J. P. Morgan & Co. is in the market for brass rods, sheets, and disks, January to May delivery. Of brass rods alone 5000 tons is wanted. The London market for spot electrolytic stood yesterday at £168. Exports of the month (including December 12) amount to only 8925 tons.

ZINC

Quotations in the past few days have been irregular, and the market on its face, is weak, yet some of the producers declare that January will see higher prices, basing their faith on fundamental conditions, which, they say, are sound. It remains true, however, that prices have continued to decline, and that 11.50c., St. Louis, and 11.75c., New York, could be done yesterday for the first quarter, with spot around 11.75c., St. Louis, and 12c., New York. For some reason zinc seems to have been more affected by Germany's proposals for peace than any of the other metals. Late December and January brass mill special is around 13 to 13.25c. Sheet zinc is unchanged at 21c., carload lots, f.o.b. smelter, 8% off for cash. Exports, December 1 to 12, totaled 1601 tons, which would indicate that they are slowing-up. The London quotation for spot yesterday was £57, or £1 10s. lower than a week previous.

LEAD

While the A. S. & R. Co. announced advances to 7.50c., New York, December 5, as reported a week ago, it has not been taking business at that level. On the 15th, however, it will begin taking orders for January delivery, the price to be fixed by its monthly average of quotations. Meanwhile the scarcity of near-by lead has continued the feature, and independents have been asking up to 8c., New York, for December delivery. That they have obtained this price has not been confirmed, but they have done business at from 7.75 to 7.90c., New York, with consumers whose needs were urgent. Intimations are heard that speculators had a hand in creating the scarcity of spot metal, but this has to be proved. On behalf of the producers it can be said that they are hampered by transportation difficulties. In the first 12 days of this month exports amounted to only 51 tons. The London quotation is unchanged at £30 10s.

TIN

The week has been a dull one, and devoid of interesting features. Importers continue to encounter difficulties in obtaining licenses to ship from England, and the supply of Banca tin is about exhausted except for a few unimportant lots. Arrivals this month total 675 tons, and there was afloat on the 12th 6228 tons, most of which is scheduled to arrive in December.

ALUMINUM

No. 1 virgin metal, 98 to 99% pure, is 63 to 65 cents.

Industrial Notes

Information supplied by the manufacturers.

Improvements in Air-Compressors

The improvements described below relate to air-compressor design of the Sullivan Machinery Co. and have been introduced during the past 12 months. They include: (1) twin design for angle-compound compressors, either belted or direct connected; (2) plate air-valves of a distinctive pattern; (3) three-pass counter-current inter-coolers.

As the name implies, the twin-angle compound compressor consists of two complete Sullivan air-compressors of the angle-compound type set side by side on a common foundation and driven by a common shaft. As in the single units of this class, the intake cylinders are horizontal, and the high-pres-

THE TWIN-ANGLE COMPOUND AIR-COMPRESSOR.

sure cylinders vertical. The inter-cooler is horizontal, and is supported by the low-pressure cylinder and its frame. The connecting-rods for both members are attached to one crank-pin. As shown in the photograph, the common driving-shaft is provided with couplings at each end, so that either compressor may be cut out in case the amount of air needed over a considerable period is less than one-half the total capacity of the compressor. The belt-pulley, or in the machine illustrated, the motor, is supported on an independent frame and on independent bearings. The air-intake for each half of the machine is independent, and each intake cylinder is equipped with a standard double-beat, total-closure, unloading-valve. When the automatic unloaders on the intake-cylinders close and after the high-pressure cylinders have pumped out the air contained in the inter-coolers (which require only a few seconds), the unloaders on these cylinders open communication with the atmosphere, so that small quantities of air leaking in around the valve-stems and piston-rods are discharged to the atmosphere without being compressed to a pressure higher than the atmosphere. This prevents heating of the cylinders and maintains a nearly perfect vacuum in which the pistons move when the compressor is unloaded. Cross-head pins, crank-pins, guides, and other connections are thus entirely relieved from the friction to which they would be subjected in case any pressure remained in the cylinders during the unloading period.

The chief object in perfecting the twin-angle compound design was to provide a compressor of elastic capacity, capable of advantageous operation at any portion of its piston displacement.

As already described, the capacity of the plant may be cut in two by removing the bolts that hold the coupling together at either end of the shaft, thus allowing one-half of the machine to stand idle; the other half, consisting of a complete, independent, two-stage compressor, then operates at full capacity and efficiency as before. If desired, for short periods, the same results can be obtained by closing one of the inlet unloaders by hand. The unloaded compressor then turns over, without compressing any air, until it is again required by the engineer. If only one-quarter of the full capacity is sufficient for the conditions, as in mine development, starting a contract, or opening a quarry, one side of the unit is uncoupled, and one intake-valve removed from each cylinder of the remaining side, thus reducing the power required for operation as well as the air delivered. For three-quarter load, both sides of the plant would remain in commission, but on one side an inlet-valve would be removed from each cylinder. The regular unloaders, of course, provide complete elasticity of output at all times, on whatever basis the plant may be for the time; and the adjustments referred to are only made when the requirements suggested above are to obtain for days or weeks at a time. The advantages of the multi-unit air-plant are thus fully realized in this new twin-angle compound type.

Another interesting feature of the twin-angle design is that it enables the plant to run at the same speed as a single compressor. Two hundred and fifteen revolutions per minute would be considered out of the question for a cross-compound unit of 2200-cu. ft. capacity; but the 1100-ft. single-compound compressors of which this Sullivan twin-machine is made up operate with complete satisfaction at this speed, and their piston-speed is relatively low so that abundant opportunity is afforded for the flow of air through the valves, and the wear of the reciprocating parts is low.

As stated above, the pulley or motor and the part of the driving-shaft between the two compressor units are supported by separate stands and independent bearings. These bearings are adjustable for either side or lengthwise adjustment, a particularly important element in motor-driven machines. None of the weight of the motor is supported by the compressor bearings proper, so that the danger of motor destruction from burnt-out bearings is greatly reduced. A separate lubricating system is also provided for the motor-bearings.

The characteristic features of single-angle compound compressors, such as balancing of reciprocating forces, with resultant smoothness of operation and power economy, small floor space, accessibility, etc., inhere also in the twin-angle compound type. These are built in five standard sizes with a full load rating of 900, 1300, 1500, 1800, and 2200 cu. ft. of free air per minute. Sullivan twin-angle compound compressors are in extended service under varied working conditions, and are amply justifying the expectations of their designers.

Plate-valves for air-compressors are offered in a variety of designs by different builders. These valves are now frequently applied to compressors operating at high speeds and aim to secure rapidity of action, wide port opening with little wire-drawing effect, absence of care and wear, and a reduction in motive power. Speaking generally, the disadvantages of this class of air-valve are increased clearance-losses, complication in construction, and danger of breakage, with resulting damage to the air-cylinder, because plate-valves are frequently inaccessible and breakage is hard to detect in proper season. The accompanying illustrations show valves of the plate type designed by the Sullivan company, which have certain points of interest and advantage. As shown in Fig. 1, this valve is of a distinctive form, shaped like a group of thin, flat fingers, made from special rolled spring-steel. Individual fingers or plates are about $\frac{1}{8}$ in. long by $\frac{1}{4}$ in. wide. When in place, these valves are rigidly bolted at one end only to a steel guard or

pressure-plate, the other end being free. The guard-plate is curved to form a rest or stop for the entire length of each plate or finger when bent or lifted by the incoming or outgoing air. The guards also equalize the lift of the valves. In lifting under air pressure, the fingers exercise a rolling or rocking action against the guard, opening first at their outer ends. In closing, the fingers roll back their seats, the fixed ends closing first and the free outer points last. Advantages claimed for the 'end-rolling' action, as it is called, are that it is free from any bodily lift that would produce a hammering or slapping effect, and that it secures freedom from leakage

FIG. 1.

FIG. 3.

in a high degree. Fig. 3. shows how the valves are set, in plates or end walls, situated between the cylinder-barrel and the heads. The left-hand plate shows the cylinder side, the right-hand, the head side, of these end walls. The position and construction of these valve-plates reduces clearance loss to a minimum for this type of valve. The inlet-valves are placed in the lower half of the plates, the discharge-valves in the upper half. The cylinder heads are fitted with hand-holes and cover-plates, to permit easy removal of the valves without disturbing either the heads or the cylinders. In the high-pressure cylinders (or in single-stage compressors of small

cooler. In all Sullivan two-stage compressors the inter-cooler consists of a nest of tubes made of copper or aluminum, substances of high conductivity, through which the cooling-water passes. In ordinary practice, the current of water enters the inter-cooler at one end, traverses one-half of the tubes and returns through the other half to the starting-point. The air is caused by baffle-plates to take a zigzag course across the tubes, and comes in contact with them three times in passing from one end of the inter-cooler to the other. While effective for ordinary conditions and with cooling-water of ordinary temperatures, there has been some call for inter-coolers of unusually high effectiveness for places where the temperature of the circulating water is high, or where the highest efficiency possible is desired. For these conditions, the Sullivan three-pass, counter-current inter-cooler has been designed. It is shown on this page as applied to a twin-angle compound 'WN-4' motor-driven air-compressor. The inter-cooling surface of this inter-cooler consists of three nests of copper tubes, through each of which cooling-water circulates, entering at one end, traversing one-half of the tubes, and returning through the remainder. The ends of these tubes are expanded into headers, the outer header being bolted against a packed joint on the outer end of the inter-cooler body, while the other header, inside the inter-cooler body, is left free to move with the expansion and contraction of the tubes. Suitable baffle-plates are placed in the interior of the body, so arranged that the air, in flowing through it, is compelled to pass three times across each nest of tubes, thus insuring a thorough cooling effect. The course of air is opposed to that of the water, thus obtaining the greatest possible cooling value from it. The tubes and the three compartments in which they are placed are housed in a rectangular cast-iron shell.

Mining Decisions

OIL LEASE—AUTHORITY OF A GUARDIAN

Surrender of an oil lease to the guardian of a minor by the lessee in order to escape liability for rentals is of no avail, unless approved by the Court that authorized the guardian to make the lease.

Ardizzone v. Archer (Oklahoma), 160 Pacific, 446. October 31, 1916.

MINER'S LIENS—NOTICE OF NON-LIABILITY

A notice of owner's non-liability written in lead pencil and posted so as to be exposed to the elements on the compressor-house and on temporary structures at the collar of the shaft which were intended to be removed before certain workmen commenced work, is not a good defense against a suit to foreclose a miner's lien.

Phillips v. Snowden Placer Co. (Nevada), 160 Pacific, 786. November 9, 1916.

OIL LEASE—FORFEITURE

Where an oil lease required the lessee to drill a well within four months or pay a minimum royalty of \$80 per month thereafter, and the lessee did neither, it was held that the lease was voidable at the option of the lessor after the expiration of the four months' period, even though no express covenant to that effect was included in the lease, and a judicial decree of forfeiture should be granted at the lessor's suit to clear his title.

Brown v. Wilson (Oklahoma), 160 Pacific, 94. October 10, 1916.

FIG. 2.

size) the plate-valves are placed in cages and arranged radially around the periphery of the cylinder-heads in the same manner as automatic poppet-valves are set on Sullivan compressors of ordinary type. Each cage contains two valves, each consisting of two fingers that run lengthwise in the cage. These are equipped with guards of the same form as those already described, as in Fig. 2.

The full advantages of the two-stage compression of air are not realized unless the heat generated in the intake-cylinder is thoroughly removed before it reaches the high-pressure cylinder. While cylinder water-jackets are valuable aids in this regard, this cooling depends in the main on the inter-

EDITORIAL

T. A. RICKARD, Editor

ACCORDING to a later ruling, every American patent runs its full life, irrespective of the time at which its corresponding foreign patent may terminate. So No. 835,120 of Minerals Separation American patent will lapse on November 6, 1923, although the original British patent expires on April 12, 1919.

WE note an item in the daily press concerning Albert Freeman, who was indicted several years ago jointly with Julian Hawthorne and William J. Morton for swindling the public by means of a mining prospectus. Freeman was sentenced to five years in the penitentiary. On appeal, he was granted a new trial and released temporarily on heavy bail. On December 10 in New York he pleaded guilty to the charge of conspiracy to defraud investors, through illegal use of the mails and was fined \$3000, which he paid. His attorney stated that he pleaded guilty to the indictment because he was "no longer able to meet the aggressiveness of the Government." It only remains for all good citizens to commend the Government for its "aggressiveness" in checking swindling through misuse not only of the mails but of legitimate industry.

GERMAN peace overtures have done as much damage as an army corps on the war-path. Wall Street cut a sorry figure during the ten days in which it was at the mercy of peace and rumors of peace. The 'peace scare,' as it is pathetically called, must have caused a great many million dollars to change hands and to that extent it made a broker's holiday, but it was a poor spectacle. However, in Japan they do things even worse. The Tokio stock-exchange had to be closed "after one of the most riotous days in its history." Of course, we do not know how riotous Japanese brokers can become, but judging from their prowess in the field of battle we may assume that it was 'some riot.' Meanwhile thoughtful men must be asking each other what will happen when the dove of peace is seen, if such a welter of speculative panic can ensue from a sound that is not particularly like the beating of her wings.

H. C. L. is a Western abbreviation for the high cost of living, concerning which a lot of nonsense is being written in blind disregard of the fact that it is mainly the consequence of a love of luxury that a period of excessive prosperity has engendered. Unless we are much mistaken this confusion of ideas extends to the mining industry, in which the intensive exploitation of ore reserves is causing an extravagance in management that is not all due to the high cost of machinery or supplies but

is traceable in large part to the rush to become rich, that is the haste to earn dividends. When the orgy of production is over, the managers of mines will have to face all the dreariness of the proverbial 'morning after.' Whether the gutting of mines is commendable or not depends upon a fundamental difference of opinion, as to whether it is proper to realize upon the ore in a minimum of time and a maximum of immediate profit or to operate a property as an investment that will last for a human lifetime. In this, as in other matters, a sane economy lies between the extremes.

INQUIRIES have been received from a number of localities in California concerning annual assessment work on unpatented mining claims. Those who desire a copy of the latest California mining laws would do well to request the State Mineralogist, Ferry Building, San Francisco, to send Bulletin No. 71, which contains the mining laws, county maps, and statistical information regarding mineral production of the State in 1915. The California law regarding annual assessment is as follows: "Sec. 1426 l. The amount of work done or improvements made during each year to hold possession of a mining claim shall be that prescribed by the laws of the United States, to wit: One hundred dollars annually." The State law makes a much-needed provision, as follows: "The failure or neglect of any locator of a mining claim to perform development work of the character, in the manner, and within the time required by the laws of the United States, shall disqualify such locators from re-locating the ground embraced in the original location or mining claim or any part thereof under the mining laws, within three years after the date of his original location, and any attempted re-location thereof by any of the original locators shall render such location void."

READERS of this paper indicate what is interesting by the letters they send to the discussion department. The prospector and his fortunes appears to be a topic that cannot be suppressed, for in this issue we have two letters dealing with it. Mr. John A. Roos makes some incisive remarks, such as that the training of the prospector has not kept pace with the training of the engineer, so that the latter has usurped part of his function as a scout. That the explorer must be an optimist, one must agree, but that he must be ignorant of scientific aids does not follow. For the suggestion of a 'Prospector's Special' we can arouse no enthusiasm, but it is in accord with those pictorial developments in modern life that the cinema typifies. However, we like

Mr. Roos's humane and humorous treatment of the subject. On the other hand, Mr. W. H. Storms finds less fault with the prospector than with the conditions that have rendered the old 'hit or miss' method of exploration no longer successful. Mr. Storms is in a position to know, for, while a technologist himself, he numbers many of the old-time prospectors among his personal friends. We commend his diagnosis of the trouble that has befallen the pioneers of mining.

ACCORDING to letters received from mining engineers still remaining in Mexico, the principal mines at El Oro are working full time and the workmen are being paid in silver. Coin is hard to get and a shortage is anticipated despite the premium offered. Small strikes among the men have been settled promptly. At Pachuca the depreciation of paper money makes business difficult. The Government refuses even to receive its own money in payment for taxes and freight. The mining companies are compelled to use gold and silver, but the scarcity of this means of exchange hampers dealings. Several strikes, due to the inability of the peons to understand the financial situation, have interrupted mining operations, but not for long. Another difficulty is the scarcity of cyanide. This has curtailed the capacity of the mills. Moreover, the exorbitant price of cyanide, caused in part by the withdrawal of large stocks bought by speculators, will render it impossible for the poorer properties to continue at work. The destruction of trains, the strikes among the railway employees, and the raids of bandits render operations so precarious that it is impossible to look ahead. Correspondents in localities so wide apart as Pachuca and Tequila agree that the one thing that would aid the existing Government in restoring order would be a loan. Without money the powers that be are helpless. On another page we quote the latest decree concerning the export tax on metals. The reduction of 3% on the gold and silver will be helpful.

HOW the metal markets are dominated by groups of foreign traders backed by big banks is explained clearly in a chapter on 'Buying Combinations in the Metal Market' appearing in the report of the Federal Trade Commission dealing with 'Co-operation in American Export Trade.' Those engaged in mining operations will find a good deal of interesting information set forth clearly in the chapter to which we refer. What these international—or, more correctly, non-national cartels and syndicates have done in fixing metal prices and in otherwise regulating the market to suit their own ends ought to be known to every intelligent mine-operator. We have referred to the subject frequently in these columns. The official report may be more convincing. Incidentally, we may refer to the controversy raging in Canada—chiefly at Toronto—over the two shipments of nickel to Germany on the submarine *Deutschland* as disclosed by the *Providence Journal*. We have been quoted in this connection, and not improperly. In that controversy we shall take no part, for it is tinged with local

politics and an evident effort to injure the International Nickel Corporation. But we do suggest, not for the first time, that a searching investigation into the metal-selling business would prove illuminating not only to the trade and to the several governments but most of all to those engaged in mining, because it has a vital bearing upon the disposal of the metallic products they are engaged in producing.

F. A. VANDERLIP is known as the president of the National City Bank of New York, an enterprising and intelligent organization that is doing a great service for American business abroad. But he is more than a banker, he is a good citizen, as is made evident by the text of the recent address delivered by him before the Bankers Club of Chicago. We would like to reproduce all of it for the benefit of our readers, but the subject is outside our immediate province and we shall have to content ourselves with a brief quotation: "A part of the country has been submerged in prosperity and its sense of proportions and relationships has certainly been dulled. Another, and a greater part, which has only experienced this prosperity in a reflected way and has viewed both the War itself and its reflex action upon our industries in a somewhat far-away and detached manner, has developed a point of view of aloofness from the world's tragedy. It has been a spectacle, but it has not gripped their souls. They look with horror on the carnage, with satisfaction on the profits, but with an unrelated sort of superiority to both, and feel that as a nation it is best for us to avoid being involved in any of the consequences. . . . To me, this seems an utter lack of imagination, a blindness of vision, a complete failure to understand the unity of the industrial, commercial, and financial world." We remember a banker early in 1893 in the Denver Club deriding the successive failures in Australia and we ventured to suggest to him that the people of Denver might feel the financial perturbation of events even in cities so distant as Melbourne and Sydney. In July of that year 13 out of 17 banks closed their doors in Denver. The warning given by Mr. Vanderlip is timely.

ON another page we give the full text of the Supreme Court decision in the Minerals Separation case against James M. Hyde. We believed that our readers would be glad to have the *ipsissima verba* of the Court, rather than an abstract or summary prepared by anybody else. However, after the text had gone to press we were notified of three errors in the printed copy of the decision as sent to us, namely, (1) in line 15, second column, of our page 944 "tenth of one" should precede "per cent.," (2) in line 20, second column of page 944 "tenth of one" should precede "per cent.," and (3) in line 12, first column, of page 945 the word "impossible" should be "clear." In announcing the close of this particular litigation, in our issue of December 16, we made some suggestions. Further comment will be deferred until the policy of Minerals Separation is announced. In

New York it is believed the decision will pave the way for amicable adjustment of the controversy—by a reasonable arrangement for royalty, we presume. The number of American infringers is given as 234 and all of them will be given a chance "to come to time." If any one of these mining companies prove recalcitrant, as we expect they will, then demands for injunction and suits for damage will be started by the successful patentees, followed by an accounting of the profit derived from the use of the flotation process. The Jackling companies are likely to file bonds so as to enable them to proceed with their operations pending a settlement, amicable or legal, as events may decide, of the controversy. The Miami Copper Company declared \$299,396 as the profit made in November on that portion of its output that was treated by flotation, namely, 120,988 tons. We note that the idea of adjudging the profit arising from patent No. 835,120 by the saving of oil, as determined by deducting what is used from the limit specified in the patent, has been brought forward in Boston. According to this ingenious interpretation of the law, the Butte & Superior would deduct the value of the 18 pounds of oil used per ton from 21 pounds—or over 1%—on the supposition that the use of any quantity over 1% does not infringe. An announcement of the Minerals Separation policy should be forthcoming at an early date.

Announcement

Our readers will have become aware, from frequent references to the subject in the daily press and in our own columns, that the price of paper has risen considerably, partly owing to the increased cost of the raw material of manufacture and partly by reason of the arbitrary action of the manufacturers themselves. The cost of the high-grade paper that we use has risen 60% during the past twelve months. This may be compared with the statement of the Associated Business Papers that the average advance among 36 publications has been 70%, the figures ranging from 35 to 250%. Thus the increased cost to us is slightly below the average; but, as can readily be surmised, it may rise further at any moment. We have been notified of a further advance on the day this is written. The net result is that the mechanical cost of producing a copy of the MINING AND SCIENTIFIC PRESS is 2½ cents more than it was a year ago. This represents an addition of \$1.30 per annum, and there is no assurance that it will not become more. At \$3 per annum, our readers pay 5.77 cents per copy, whereas the direct cost—of paper, printing, and postage only—is 10 cents at this time. All of this is stated in the frankest way in order that our subscribers may understand the reason for the decision, now announced, to increase the subscription to \$4 per annum. At that figure it is still \$1 less than the rate charged by other technical journals of the same class. We are the less unwilling to take this step as it is one that has been taken by some of our contemporaries, for similar reasons, and because it is our intention to incur greater expense in making the MINING AND SCIENTIFIC

PRESS increasingly valuable to all those engaged in mining. We take this opportunity of announcing that Mr. W. H. Storms, editor of this paper before 1906 and a mining engineer of varied experience, particularly in the actual work of directing underground operations, has rejoined the editorial staff. In addition, we are glad to state that Mr. Courtenay De Kalb, associate editor from 1908 to 1910, and a technical writer of acknowledged distinction, combining the experience of the mining engineer and metallurgist with the rare faculty of clear and incisive exposition, will also become associated with the present editor in the early days of the new year. The division of editorial work will enable Mr. De Kalb and Mr. Rickard to make frequent journeys of observation to the principal mining regions and give the readers of this paper first-hand information conveyed in an illuminating manner. In short, the MINING AND SCIENTIFIC PRESS is growing with the industry to the service of which it is dedicated.

Electrolytic Zinc at Trail

In this issue we conclude a description of recent changes in smelting practice at Trail. Of these changes the most interesting is the successful introduction of electrolysis for the extraction of zinc. While the methods of leaching and precipitation in use are still undergoing improvement from month to month, enough has been done to demonstrate the success of electrolytic refining and fully to justify the metallurgical designs of Mr. E. H. Hamilton, with whose name the new departure is not improperly identified.

It is worth while to review the events that led up to this result. Electrolytic zinc in British Columbia was associated with the name of French. Andrew Gordon French was a Scot from Glasgow; at one time he was technical manager of the refinery business conducted by the Sheffield Smelting Company, at Sheffield, in England. In 1909 he came to Victoria, B. C., and made experiments on zinky ores, following a little experience that he had had with the Parnell and similar obsolete processes at Swansea, in Wales. His work at Victoria was sufficiently successful to lead to the organization of a company intended to exploit the process he had elaborated. In 1911 he moved to Nelson, where he obtained the use of an abandoned municipal power-plant and conducted experiments on a larger scale, producing electrolytic zinc of high quality from various ores mined in the Slocan district. This came to the notice of the Consolidated Company at Trail and it is stated that representatives of the company went to Nelson to make tests on the Sullivan ore at French's plant. The Sullivan mine had been acquired by the company in 1911 and it gave promise of becoming a big thing. The tests made at Nelson were sufficiently encouraging to cause the Consolidated Company to make a contract for the purchase of the sole rights to the French process in Canada, but nothing seems to have been done until 1914 when the process company appointed one of its directors, Mr. Thomas French, the son of the inventor, then deceased,

to advise the Consolidated Company in the erection of a 1-ton plant. What happened then is a matter of controversy. Mr. French asserts that obstacles were placed in his way but that in spite of this lack of co-operation the plant was worked successfully in accordance with his directions. The contract, he says, was not fulfilled, so the French Complex Ore Reduction Company, as the process syndicate was called, cancelled the agreement and withdrew from further participation in the experimental work at Trail. The gentlemen at the big smelter are unwilling to ventilate the dispute that ensued, but we infer that they found in Mr. French's method an echo of older patents and in his process too many details requiring further elaboration.

On his return to Nelson, Mr. French continued to have the backing of Mr. J. O. Patenaude, a local jeweler and a sagacious man of business. Mr. Patenaude took steps to obtain Government assistance, and succeeded, after a favorable demonstration of the process had been made at Silvertown on zinc-lead ore from the Standard mine. With the support of Mr. R. F. Green, the representative for the Kootenay in the Provincial parliament, he secured a grant of \$40,000 for the erection of a plant. He also obtained the use of the old electric smelter at Fairview, on the outskirts of Nelson, where last summer an electrolytic plant was being built under the supervision of Mr. French. This plant includes a McDougall roaster left from an earlier metallurgical effort. The leaching department includes two vats and a filter-tank aided by vacuum. The electrolytic department contains 37 cells. It is expected to add a lead refinery, using the Pattinson and Parkes methods for separating the silver. Mr. French claims that he can extract 90% of both metals from a 15% zinc and 30% lead ore. He will use sheets of rolled zinc for starting and then a lead anode. The show of secrecy concerning details may be excused on account of the feeling engendered by the controversy with the Trail management but it seems to us that the Provincial government, as a patron, should insist on the publication of the fullest information in return for its subsidy.

Into the controversy over patents it is unprofitable to go. It is proper to state, however, that Mr. French claims originality (1) in the use of manganese to prevent corrosion of the cathode and to maintain the purity of the electrolyte; and (2) in the use of sodium bisulphate, or 'nitre-cake,' which is added to the ore while it is being roasted, for the purpose of converting the metallic oxides into sulphates. It is asserted also that the zinc sulphate goes into solution before the iron sulphate, which remains undissolved if the leaching is stopped at the right moment. He further asserts that his patents are being infringed both at Trail and Anaconda, but as he confessed to the present writer that he had not made a search of the patent record, this assertion may be imputed to the natural eagerness of an inventor. The Anaconda management has looked into the matter and finds that French's American patents do not conflict with the process in use at either the Washoe or the Great

Falls plants, which follow the method designed by Mr. Frederick Laist. The Consolidated Company acknowledges the taking of an option on the French patent, for which a royalty was to be paid in case it was used, but the metallurgists at Trail assert that after French had erected and run his trial plant, they found it unsuitable and since then they have developed another electrolytic process. At Trail sodium sulphate is not used, and as for manganese, that exists in the Sullivan ore. Presumably if a reagent is a natural constituent of an ore, and produces sundry reactions of a beneficent kind, the use of it cannot be claimed as an infringement, even if the patent be validated. The manganese idea in electrolytic zinc refining is like that for the formation of magnetite to protect the lining of a copper converter, as patented by Krejci and Wheeler; it is difficult to prevent the formation of magnetite under the conditions specified and the desired result was obtained in converters long previous to the publication of the method.

Passing from these disputable points we come to the main question of the dependence of economic success in electrolytic refining upon cheap electrical energy. It is difficult to obtain accurate information concerning the cost of power. The big metallurgical company usually obtains its electricity from a power company and an inquirer is told the figure in the contract, but the power company is likely to be a subsidiary of the smelting company, so that the bedrock price is not disclosed. At Trail a nominal figure of $\frac{1}{3}$ cent per kw.-hour, or \$20 per hp.-year is quoted. The little plant at Nelson is said to obtain its power from Bonnington Falls at \$13.50 per hp.-year. It may be taken, as a rough estimate, that in the West it is possible to generate power for \$10 per hp.-year, this sum including attendance, maintenance, and interest on a 20-year redemption of the capital involved. Of course, the cost depends mainly on the rate of amortization, which is based upon the estimated life of the enterprise. In a new country most people do not look far ahead and enterprises change hands at comparatively short intervals—hence a high rate of amortization; but given a metallurgical plant like that at Trail or Great Falls, well-established and strongly supported, assured of an abundant supply of ore, it would be safe to cut down the interest for redemption to a low percentage over a long period. What the cost of producing zinc in this way is has not been disclosed. That interesting financial gossip, the *Boston News Bureau*, stated recently that at Trail "the actual cost of making zinc from a 10% zinc concentrate should never exceed two cents per pound, and where power is \$10 or \$12 per horse-power, it should not exceed $1\frac{1}{2}$ cents per pound." Presumably 'never' stands for 'not' and the cost mentioned may be meant to cover only the roasting, leaching, and precipitation, not the mining and concentrating. The statement is not clear, but it is likely to be taken to mean that spelter can be made for 2 cents per pound as against an average pre-War cost of 5 cents. If a guess is permissible we would hazard 4 cents as the cost of producing zinc from the Sullivan ore at Trail.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Prospector Again

The Editor:

Sir—I have read with interest the views of many as to 'What is the Matter with Prospecting?' Having mined and prospected in several States during the last ten years, my views as a prospector may be of interest.

The education of the prospector has not kept apace with that of the engineer. Were the problem put to me, I would analyze it by dividing prospectors into three classes: Class A would include the men who through their powers of observation, technical reading, and similar accomplishments, have placed themselves in a position to form a fairly good idea of prospective mining values; they are the scientific prospectors. When our prospector gets this far along, he gains something of the engineer's pessimism and is likely to confine his search to located ground, for a lease or a bond-and-lease on property, the value of which a less experienced owner is not aware. The hardihood and natural liking of the game should make this man of value, but the engineering staffs of the large companies seldom employ him and few have the means to go to the hills for the season.

In Class B, I would put those who prospect by the hit-or-miss method. Early in the career of one of this class he is likely to find a cropping imposing as to size but barren of possibilities. Not being able to appraise same, he decides to read up, so he sends for a professional paper on his district; upon opening it he finds a photo-micrograph of a quartz mica-hypersthene-diorite and is dumb-founded; turning farther, he finds he never could pronounce or remember such a name, and finally decides that anyone who would call granite by such a name is crazy. Next he meets an older Class B man who tells him that the names, and such, are for the same purpose as a doctor's prescription in Latin, namely, so you cannot fill it at the grocery, and that you can't tell a thing about the rock beneath except by digging, and he digs. A little rightly-applied information would start him toward Class A. He is also a loss.

In Class C, I will put the man whose education is about equal to figuring up a grub bill. He is as likely to hold the technical man in great regard as not, or to say "Shucks, one of them book learnin' fellers told old Jones he'd never hit nothin' and look at his mine now, workin' six men." But don't ridicule this man, he's likely to have eyes that see and a memory a mile long, and he makes a strike oftener than a Class B man. He doesn't carry a head full of technical phrases, but a picture gallery crowded with rock-pictures gathered through the

years as miner, mucker, and prospector. He's more of an explorer than A or B, always with an eye for placer and for such formations as he has seen that held ore. An optimist? Well, I guess yes.

Now, say all three have a claim of about equal prospective value for sale. A will generally be fair in terms, but B—well, he wants a million or two cash and the trusts 'ain't goin' to get his claim for a song." C may ask a big figure, not knowing the value of money, but stack a little pile of gold in front of his eyes and you have generally bought something. Now, A is apt to keep abreast of the times, but put him in the field or he's a loss; B and C need the handling advised for a mule—just convince him you know more than he does, by using proper language. No, I would not club him over the head with anything he could not digest. He'd fight shy. "But," you say, "how can we get to him as an individual, for he's scattered all over the Cordilleras, and he holds us in such light esteem, he'll be shy?" Well, the feeling is mutual in many cases, so you've got to take a lesson in pulling together, not bucking, or you'll both continue to ask why good properties are getting harder to find. Generally speaking, you are older and should know more than he does.

Now here's my plan, Utopian as it may seem to some, and it calls for co-operation by everyone directly concerned in the mining industry. Say I've got all this co-operation that the U. S. G. S., A. I. M. E., or other associations or individuals can give. The U. S. G. S. should handle this work, for they are equal to it, if the pork-barrel doesn't get all the kale. Co-operation comes in here, for it takes money. A dozen geologists, good 'mixers,' to begin with, should receive a special treatment which would leave them just ordinary humans, able to talk mining to B and C prospectors so they'll 'savy.' I'd get six specially designed railroad-cars and in big letters, label them the 'Prospector's Special.' Take the moving-picture outfit along and in the mining towns or all places with mineral possibilities, hire the town-hall or theatre for a night or two. Show mining scenes, prospecting outfits in the field, croppings of prominent mines, and where possible, from prospect to mine. Give a little talk at the same time, the idea being to convince people that prospecting is not always humbuggery, but an honorable calling; one in which to strive to excel.

You say this is not educating the A-B-C mixture. No, it's just boosting the game, encouraging him a bit, putting him right with the public. We'll go with him to the ear—he's read the announcements and has come out of the hills. We're going to be here a week, you know,

not a fly-by-night. Into the car comes Mr. Rainbow Chaser. Mr. Mixer doesn't see the bacon tracks or need of a shave, but gives him the 'glad hand' and up a notch goes Mr. Geologist with his more primitive brother, and his interest is excited now that he feels at ease. He sees cases of rock ingeniously arranged; croppings from the 'Wonder' and ore from below. Croppings from above orebodies predominate—that is his problem. He can't remember the scientific names put there for A, but he can judge rock and read values. The croppings will be observed so minutely that he'll have a collection worth while for the picture-book he'll open in his head as he goes back, not a batch of meaningless words.

In the 'rare' mineral collection he has seen a sample of stuff he passed over years ago and no one of his friends knew what it was. He knows now, for the picture-book has kept its colors well; it is likely to result in a discovery. Also he's brought along rock for comparison and he takes back a publication that reads like a story-book in non-technical language and after he's read it through he has an idea of primary and secondary orebodies and what to waste no time over. He's on his way to Class A, his prejudice scuttled and sunk with all hands, a missionary now, not a knocker.

It is 1925 now and we read in a 1916 M. & S. P. that someone said all worth-while orebodies have been found and we laugh as we read of the new mines coming in and the generally prosperous condition of mining and decide that most assuredly do advertising and education pay.

Ravalli, Montana, November 25. JOHN A. ROOS.

The Editor:

Sir—I have refrained, until now, from attempting to add to the already too heavy burden of the prospector, who, a number of our friends insist, has "something the matter with him."

I have known the prospector quite intimately for many years, I have watched his career with interest, and I have reached the conclusion that the trouble he has experienced in recent years is not so much his fault after all. The 'matter' is that there is an entirely new dispensation in affairs that affect him profoundly. The old-time prospector is dissatisfied with his present opportunities for finding rich ore deposits, and even more so with his chances of turning any 'find' he may make into a sudden fortune. By nature he is an optimist, with an inborn faith in his own ability and judgment, as far as the search for and the ultimate discovery of a rich mine is concerned, and he used to feel entirely competent to sell a promising prospect to good advantage should he be so fortunate as to find one.

A few years ago the prospector went into the hills alone or in groups, and 'ran over' the country, looking for minerals. So rapidly did he move that most people thought his work was done carelessly, and that he was prone to overlook much that was valuable, but the history of most mining districts shows that, generally speaking, such was not the case. Unless a vein or ore deposit was obscure, he was pretty likely to discover it and it was

only those deposits that required considerable geological knowledge and prolonged exploratory work before discovery that escaped him. The first men to go up Gold Run in the Black Hills discovered and located the Homestake; any man that ever saw a mineral deposit, who might have chanced to run across the huge outcrop of the Bunker Hill & Sullivan mine, in the Coeur d'Alene, would have at once recognized it as a great possibility and promptly have located it; and so with a great many others. It is true, some of the best mines, like the Granite Mountain, at Philipsburg, Montana, were not rich, nor particularly favorable at the surface, but the good ones usually gave sufficient evidence of their potential value to make them look attractive to the prospector.

What was it that made the business of prospecting so alluring to a large number of men throughout that wonderful period to which we refer as 'the early days'? It was the constant hope, not ill-founded, of finding rich ore that could be shipped at good profit, or the belief that any discovery possessing an attractive appearance could be sold at a price which would insure to the fortunate discoverer at least a competency, if not a large fortune.

A party of several prospectors found the McCracken mine years ago in western Arizona. The ore was rich, and in a short time the lucky discoverers sold out for a large sum. One of them chartered a special train to take himself and family on a trip to Washington. He lasted a year or two and then, flat broke, returned to his old business of prospecting. But was he again fortunate? Indeed, he was. He made two or three fortunes later by lucky discoveries, though none of them as valuable as the first. A party of ten men went prospecting in the Black Hills in 1879. They had been out but a few days when they found a large mass of schist and quartz carrying gold. They named it the Grand Junction. Before they had done development work to the extent of \$2000 they sold out for \$125,000 cash. The mine was not worth it, but they got the money just the same. Another crowd discovered a small rich streak in a big vein at the side of the road a few miles from the Grand Junction and not far from the town of Custer. They called it the Telegraph mine, and within a few weeks disposed of it for \$75,000 cash. Again, the property was not worth the price, but that was learned later. The Quijatoa in southern Arizona, a rugged hill on the side of which was a plaster of high-grade ore, was discovered, located, and sold with scarcely any development work, for \$450,000. It was one of the dismal failures, but the losers were millionaire Comstock miners and could stand it. The experience did not deter them from taking other chances elsewhere.

These are but a very few instances of large fortune, quickly acquired by the humble prospector. The annals of mining in the West teem with just such stories of rich strikes, high-grade ores, fortunes almost over night, and stampedes from place to place—White Pine, Pioche, Reese River, Tuscarora, Tombstone, the Black Hills, Leadville, and Cripple Creek. More recently we have

had Nome, Tonopah, Goldfield, National, and a dozen others of less spectacular character, and now it is Oatman, in Arizona.

In those days the prospector was all right. He was independent and needed no other incentive than the opportunities of his calling to urge him to seek success. But now—it's different. In those days he penetrated everywhere; no desert was too threatening, no mountain too rugged, no forest too impenetrable, and no danger too great. He went, he saw, he located, and sometimes he won. The easy good things—either ore deposits or capitalists, are numerous no longer. The prospector still goes afield, but the railroad and the automobile have to a great extent displaced his burro and pack, greatly reducing the dangers and hardships of his occupation, but if he has been in the game very long, he no longer really expects to sell a ten-foot hole for a half-million dollars more or less. He knows that the prospective purchaser, if he ever gets one, will be discriminating, exacting, and hard to please. He knows that the man with the money is no longer satisfied to cheerfully hand out his certified check after giving the prospect the 'once-over,' for if he is 'wise to the game' he sends an experienced engineer and geologist to investigate. If the report is favorable, he may send another, and possibly several others in succession. Not only does he have a most rigid inquiry made as to the amount of ore available, but he wants to know its probabilities for the future beyond what actually has been exposed by development. Then there is the question of the metallurgy, which has to be investigated to a finish. The capitalist or his engineer must know the methods to be employed, the cost, and everything else that in any way has any bearing on the matter. After having ascertained all concerning the property that can be learned, and as much as possible of that which lies wholly in the future, he coolly calculates all the chances for and against success, enlarging on the latter, and finally makes up his mind. If the prospector makes a sale, it is at a price far below his hopes, and with terms attached that would make an old-timer shiver, if not quit the game in disgust.

The prospector has learned that mining has been divested of much of its glamor—has been reduced to a scientific calculation of cold dollars and cents. Capitalists no longer run a race with each other over hundreds of miles of mountain or desert to be first to reach the owner of a prospect. Today the prospector will be fortunate if he can succeed at all in bringing the attention of capital to his fairly well-developed property. Not only must he have an attractive showing, but it must be easily accessible, preferably by railroad, and if necessary, by automobile. Long stage-coach rides and journeys in the saddle are no longer considered as trifles by the wealthy comfort-loving investor. The prospector must be able to show that not only has he an excellent prospect, but he must be able to show that he also has available, if not actually owning, water and timber, and some inexpensive means of securing or generating power, for all of which he must be willing to accept a moderate

price, and then, worst of all, he must wait for months, or even years, before he can get his money.

There is no one thing alone that is the matter with the prospector. It is the entire change in conditions which have come about in recent years, that have nearly driven him out of business. A return to the old-time reckless way of doing things is neither possible nor desirable, but if the prospector can get into a new field affording anything like the opportunities of 30 to 50 years ago, he will quickly be in evidence once more, and will flourish too, but never again in the same old way.

San Francisco, December 25.

W. H. STORMS.

Black Sand

The Editor:

Sir—During the summer of 1900 I had an opportunity of witnessing the natural concentration of beach-sand mentioned by Mr. Herbert Lang. I was operating a string of sluice-boxes on the beach, about nine miles above Nome, and at the time when the big storm came, in August, the sluicers had almost completed the job of washing that part of the beach lying between high-water mark and the tundra, for almost 10 miles along the coast west of Nome. The so-called bedrock was simply a clear white sand, on which the pay-streak usually lay in alternate layers of black sand, one to four inches thick, then ruby sand of about the same thickness, then the top dirt of about four feet. Sometimes the pay-streak was not on the white sand, but a foot or so deep, and again there would be several streaks of black sand at different depths, and always the ruby sand over the black sand, with the classification of each material very clear.

Of course, the beach had been pretty well turned over in 1899 by the rocker men, who simply stripped the top dirt and worked the richest of the black sand in their rockers, but they overlooked patches here and there, so that I was able to see exactly how the original formation had lain. In one of these patches the pay-streak was fully six inches thick, and about 12 ft. across, and carried about \$1.50 to the pan. This was a little bonanza. Well, the big storm came and raged for three days, leaving the beach in exactly the same condition as it was before any work had been done. Naturally we were curious to know if there was any 'pay,' and with the first hull we began panning. To our amazement we found a thin streak of black sand less than a quarter of an inch thick, and carrying gold directly on top of the whole formation. We immediately set up a 'long tom,' which was simply the end box from our sluice in which we had ten feet of plates. Turning in a small stream of water from the tundra, we began shoveling in, using a pyramid grizzly to keep the coarse material from scouring the plate. Two of us worked about six hours when the storm drove us off the beach again. We cleaned up the amalgam, retorted it, and obtained close to ten ounces of gold which at that time had a trade value at the Nome stores of \$16 per ounce. After the storm had subsided again, we prospected in vain. The black sand and ruby sand

were there in streaks, just as they were originally, and there was some gold. We tried at different places along the beach for miles and could make about three dollars per day per man, but we never found what was considered good 'pay.'

FRED, G. TYRRELL.

Selby, December 4.

Handling Mexican Labor

The Editor:

Sir—Sometime ago I had an opportunity to go underground at the Dos Pilares mine, near Nacoari, in Sonora, Mexico, and there I saw a method of handling Mexican laborers that was entirely new to me. With a foreman as guide, I and two friends stepped on the platform of the cage, which took us down into the mine. As we approached the stope, through a cross-cut from the shaft, the sound of music came to my astonished ears, nor did it cease when we entered the stope. Here was a great chamber nearly 100 ft. square cut in the heart of a great orebody, and not a single stick of timber for support was in sight. Haste was being made, however, to fill the stope with waste drawn down through a raise connecting with a big glory-hole on the surface. The chamber was well lighted by numerous incandescent electric lamps. Near the centre of the excavation, but a little to one side, sat a Mexican youth at a table over which was suspended one of the lamps. Over against a wall, a young fellow lounged carelessly while vigorously playing a harmonica, which he encompassed with his cupped hands alternately uncovering and again closing his hands over the instrument with the rhythm of the music. Near him three or four other men were stretched out full length on planks, apparently sleeping. Not far away several others were enjoying a game of cards, a number of men standing by interested spectators of the game. The appearance of the foreman made no difference to the men in their pleasant diversions. The fellow with the harmonica never missed a note, the card players seemed unmindful of his presence, and the sleeping ones continued to sleep. There were, perhaps, 60 men in the stope, of whom all were at work except those engaged as described. Each man wore on his left breast a disc of brass, displaying a conspicuous number. Those who were at work were either shoveling waste rock into a wheelbarrow, trundling a wheelbarrow from the shoveling place to the 'fill' at the opposite side of the stope, or taking it back empty to be re-filled. As each man with his loaded barrow passed the youth at the table, he would call out the number of his tag, whereupon the clerk would tally a mark opposite the number called. At the end of the shift, each workman was credited with the number of loads he had moved from the shoveling place at the foot of the raise to the fill across the stope, and on this basis he was paid—a good scheme, no work, no pay. The foreman asked: "Ever see anything like this before?" I replied that it was entirely new in my experience, and he remarked, "Well, it's a good thing to remember. We have to treat these men much like children, and we have found that it works fine." It un-

doubtedly did, for the stope was being filled rapidly and cheaply, and the workmen all appeared to be well satisfied.

Berkeley, December 22.

Stamp v. Ball-Mills

The Editor:

Sir—I have watched the discussion of this subject with much interest. There is one point that does not seem to me to have received sufficient attention. The only weak point about ball-mill operations in my experience is the wear of balls and lining. I have not seen any statement, in pounds, of the balls and lining consumed per ton of ore pulverized from a given size to a given mesh with the newer types of ball-mill such as the Marcy or some other modern ball-mill operated in closed circuit with a classifier and equipped with chrome-steel or manganese-steel lining, and where balls of an equally good quality were used. I had an extensive experience with an early design of central-discharge ball-tube mill 6 by 5½ ft., in which white iron linings and balls were used. The consumption of balls and linings was about four pounds per ton of hard flinty Republic quartz pulverized from ¾-in. size to about 20-mesh, when operated at a capacity of 100 tons daily. The mills of more recent design have developed a considerably higher capacity. A coarse feed from the rock-breaker—say, a 2½-in. size—undoubtedly reduces the wear of balls and lining, and the use of high-grade chrome or manganese-steel balls and linings will undoubtedly be helpful, but I have seen no data giving the exact wear of this better-grade material. Mr. Millikan once told me that in the dry-crushing ball-mills used at the Golden Cycle mill, where a good grade of imported manganese-steel ball was used, the consumption of balls was 0.7 lb. per ton. That would not be a bad showing in comparison with the average shoe-and-die consumption with stamps. There seems to be no longer any question but that the ball-mill has the better of the stamp on all other points. For a given tonnage it is very much more economical in first cost, cost of installation, floor-space, power, and simplicity of operation, and when running in close circuit with a classifier, it will do a wider range of work, and it can be manipulated so as to prepare any desired product. The only question is this: Is the consumption of balls and linings enough heavier than the wear of shoes and dies to make the old stamp battery or the combination of stamps followed by Chilean mill or pebble-mill more desirable in a remote district where the transportation of balls and lining would be both expensive and difficult? If the metallurgical department of the MINING AND SCIENTIFIC PRESS would collect the results of recent experience with different mills using the different types of ball-mills and varying grades and designs of lining, and varying grades and sizes of balls and the practice as to size of feed and mesh of finished product, it would perform an important service to the metallurgical profession.

Dolom, Alaska, November 20.

TWO VIEWS OF THE INTERIOR OF THE ELECTROLYTIC ZINC DEPARTMENT.

Electrolytic Refining at Trail—II

By T. A. Rickard

ELECTROLYTIC PROCESS. The solution enters as a clear slightly amber liquid containing 6 to 8% zinc with 0.002% iron. The buss-bars from the generator-room, as they reach the 'tank' or electrolytic cell, are enclosed in cast-lead to protect them from corrosion. Each buss-bar is fused to the top of the cast-lead anode (30 by 25½ in. and ⅝ in. thick) to ensure perfect connection. The buss-bar connected with the cathode of the alternate cell consists of two copper plates that grip the cathode support, also of copper. The current passes from the lead anode into the solution, now properly called the 'electrolyte,' and thence to the cathode, which consists of a plate of aluminum, 24 by 27 in. and ⅛ in. thick. This is supported at one end by a copper lug, connecting with the buss-bar, while the other end has an iron bar or lug insulated by resting on a strip of wood lying on the lead of the buss-bar. The cells are in pairs. From the buss-bar along the central axis of one cell the current goes to the next cell. The voltage is 3 to 3.5. The consumption of electricity normally is 2.2 kw.-hr. per pound of spelter. The slight smell of acid recognizable in the building is caused by the bursting of bubbles of oxygen and hydrogen liberated by the electrolysis of water in the solution at the anode. When entering the room the solution has a temperature of 25 to 30°C. After repeated electrolysis it emerged at a temperature of 55° on the occasion of my visit; it is now kept down to about 35°C. The solution entered neutral, and issued with a 5 to 6% acidity. The electrolyte, as we have seen, becomes heated as it circulates through the cells; therefore an effort is made to cool it, especially in the lower cells, by inserting coils of lead pipe through which cold water flows. Fortunately, at this plant any quantity of pure cold water is available, so that this difficulty has been overcome satisfactorily.

The acid electrolyte, after leaving the cells, is returned by gravity to tanks in the leaching-room. From these tanks the solution is raised to another tank on a higher

level, where the acidity is increased to the required proportion by the addition of fresh acid through a pipe from the sulphuric acid plant.

This electrolytic plant then consisted of 14 sections of 32 cells each. The whole equipment has been doubled. Of the 14 sections, one is lined with lead and 13 are made of concrete, protected with P & B paint covered with asphalt. Each section produced 2½ to 3 tons of spelter per working day. In starting with new lead, the anode is coated with manganese dioxide, present in the solution and extracted from the ore itself, as explained to me by F. S. Willis, the superintendent of this department. The manganese coating renders the lead insoluble. Also it performs the highly important function of oxidizing the iron in the electrolyte from the ferrous to the ferric state, the latter being precipitated, while the oxygen from the decomposition of the zinc sulphate serves to re-oxidize the manganese, so that it is again ready to act as an oxidizer.

An electric crane runs above each series of cells, and at one side of the room a transfer-crane makes it possible to shift material from one series of cells to another or to the melting department. Porcelain insulators are placed along the sides and along the centres of the cells to support the buss-bars.

The cathodes are hung in cold water in order to remove any free acid, before stripping. The zinc deposited on the aluminum is detached in sheets by aid of a chisel-bar. Each sheet averages about 9 lb., so that 18 lb. is taken from a single cathode. The yield ranges from 5 to 40 lb. per cathode. These sheets are piled in 1000-lb. lots and taken by the crane to the melting-room. Thin sheets of zinc will take fire, or oxidize, before melting in a reverberatory furnace; therefore the fine stuff and scraps of cathode zinc are melted in graphite crucibles, placed in an oil-fired furnace, where the supply of air can be restricted. Metallic pots of any kind are objec-

tionable because the zinc is likely to absorb impurities from them. Hence a brick furnace is preferred. The cathode-sheets themselves are fed into a coal-fired reverberatory furnace, having a hearth 6 by 12 ft. and a 4-ft. fire-box. A brick ridge is built across the hearth to hold the dross back from the wall. The dross is removed by skimming through the charging-door once every 24 hours. The capacity of this furnace is 20 tons of metal. The melting is done in half an hour—the slower the better, as it hinders oxidation. Any oxide found in the furnace is returned to the acid solution and re-treated. The cathode-sheets yield 93% of spelter suitable for shipment. Eventually the missing 7% is recovered. It is a question whether to treat the dross (82% zinc) on the spot or send it to a zinc-retort smelter. At present it is being re-treated. The metal is sampled by boring a half-inch hole in every 50th bar or else the spelter is cut by a power-driven saw and the saw-dust used as a sample. On August 17 the plant produced 39,975 lb. of spelter, which was 99.801 fine, the impurities being 0.04 lead, 0.009 iron, and 0.15 cadmium. As the process is being developed and the difficulties surmounted, the impurities in the spelter are being further reduced. The production is now 70 tons per day.

COPPER. This electrolytic plant, at present, consists of 96 cells, each with a capacity of 10 tons of solution. Only the first half of the equipment was at work in August. The copper to be refined was cast direct from the converter, but the new melting-furnace, I am informed, is now finished. The cast anode in the electrolytic cell weighs 320 lb.; it remains in the cell until 92% of its weight has been dissolved by the acid solution, or electrolyte, which consists of 14% copper sulphate, 14% sulphuric acid, and 72% water. When the proportion of copper sulphate increases above the normal, the excess is removed by withdrawing a portion of the electrolyte (to evaporate it into crystals of bluestone), replacing it with fresh acid. The absence of effluvia and the freedom from gas are noteworthy in this plant. It has been modeled on the Walker design; indeed it was erected after consultation with him, Arthur L. Walker, professor of non-ferrous metallurgy in Columbia University.

The anode is suspended by two copper-wire loops, which are cast into the anode and enable it to hang from a round bar (also of copper), one end resting on the buss-bar, which transmits the electric current, while the other end rests upon an insulating block of wood*. I give these details for the sake of those unfamiliar with electrolytic practice.

Starting-sheets of hard (antimonial) lead, from St. Louis and having dimensions of 26½ by 41½ by ½ in., are being used just now, in lieu of the customary sheet of thin (¼ in.) copper. This, which constitutes the beginning of the cathode, is rivetted at the bottom between two horizontal copper bars (½ by 1 inch), so as to hang vertically in the solution. The copper precipi-

tated upon the lead cathode is stripped every day, yielding 5 to 8 lb. of copper on each face of the cathode. These sheets will serve as starting-sheets, on which the cathode copper will accumulate, to the weight of 150 lb., to be removed, washed, and melted subsequently, yielding metal 99.98 fine.

For the benefit of the unsophisticated, I may state that when an electric current is conducted through a solution, it decomposes that solution, causing a rearrangement of the molecules and a movement of particles called 'ions' in opposite directions. Some go with the positive electricity to the negative pole or 'electrode,' called the 'cathode,' while others go to the positive electrode, or 'anode.' The solution is called an 'electrolyte,' and the action is called 'electrolysis.' As Edgar A. Ashcroft says: "When electricity is passing through an electrolytic medium, disruption of chemical affinities is the result." To this I may add that the theory of electrolysis rests mainly on Faraday's idea of the actual dissociation (ionization) of the constituents of the electrolyte and his inference that the quantity of an element or 'ion' set free by a current of electricity is solely dependent on the amperes, or volume of current used, not the voltage.

The gold and silver together with other impurities in the anodes become concentrated in the slime that is deposited on the bottom of the cell as the anode is dissolved by the electrolyte. Likewise in the lead refinery, the precious metals pass into the slime. This slime, from both refineries, is collected and dried. The drying and roasting are done while the slime lies in a steel pan-car, exposed to the waste gases from the silver and doré furnaces. As soon as the drying is finished, the process of combustion is started by the oxidation of the antimony, also present in the slime.

This product is then melted, without flux, in a small reverberatory lined with magnesite brick. The antimonial slag is skimmed into a pot and 'hard lead' is eventually obtained from it. The copper rises next as an oxide slag and is skimmed. Then the doré metal (containing 970 parts gold and silver, predominantly the first) is ladled and cast into bars (each of 1000 to 1200 oz.) ready for parting. Two kettles each holding 7000 oz. are used. Sulphuric acid, 94% pure, is added and boiling is maintained for 8 hours. This puts the silver into solution as sulphate, the gold remaining as a granular powder, which is washed, dried, and melted into ingots. The silver solution is siphoned into two lead-lined tanks and boiled in the presence of copper plates, which precipitate the silver, while an equivalent amount of copper passes into solution as sulphate, which goes to the bluestone plant. I saw a car loaded with the 'cement' silver, washed from the copper on which it had been deposited, and noted that the surface of the silver had already been darkened by light from a window. The copper sulphate is pumped to another building, where it is evaporated to 45° B. and allowed to crystallize. This first and usually impure crystalline product is dissolved in boiling water; the resulting solution of copper sul-

*Mr. Hamilton informs me that this system was temporary. Anodes and cathodes provided with bugs are now being used.

phate is then placed in tanks in which are hung strips of lead upon which crystals of 'bluestone' are formed as the solution cools, the cooling being assisted by the injection of air. The bluestone is detached while the mother liquor drains back into the vat. Most of this bluestone is sold to farmers in Manitoba for killing 'smut' on wheat, and about two tons (out of the 88 tons made per month) is sold for use in the gravity-cells of telegraphic apparatus. Some of it is also sold to fruit-farmers to make the Bordeaux mixture, or spray, that kills the insect pests.

LEAD. In this plant I saw, first, the making of starting-sheets. The lead is melted in a kettle and is ladled into a 6-inch trough so as to pour or spread over an inclined steel plate, upon which the metal cools instantly, leaving a sheet of lead, $\frac{3}{8}$ inch thick, 39 by 27 in., the edges of which the operator trims with a knife and then peels off the steel plate. In 8 hours he makes 4000 sheets. These are taken into another room where they are smoothed and one end wrapped around a copper bar. Then the operator puts a band of paint at the solution-line of the lead sheet, so as to prevent it from being corroded by the electrolyte in the cell.

The cells, which are made of concrete, are 408 in number and have a total capacity of 100 tons of lead per day. The lead anode, cast at the blast-furnace, weighs 312 to 320 lb., and is reduced 80 to 85% before being re-melted. The starting-sheets have been described. Two cathode deposits are 'pulled,' or stripped, for each anode consumed. An average of 135 lb. is obtained at each stripping, or 270 lb. per cathode. The electrolyte in the lead cell contains 10% hydrofluosilicic acid (H_2SiF_6) and 5% lead fluosilicate ($PbSiF_6$) in water. The solution maintains its composition well, but there is a small loss and even a slight decomposition owing to chemical instability, so that fresh acid has to be added once per week. The lead does not accumulate in the electrolyte. Of course, this stability of the electrolyte is an important factor in the process, as it was explained to me by John F. Miller, the superintendent of this department.

The slime containing the precious metals that remains on the anode is washed off, collected, dried, and treated in the manner already described.

The electrolytic lead produced at Trail averaged in December, for example:

Gold	0.0027 oz. per ton
Silver	0.6126 " " "
Copper	0.0026%
Iron	0.0068%
Antimony	0.0075%

The electric current as received from Bonnington Falls has a voltage of 50,000, which is stepped-down to 2200 volts. The load at present is 8000 kw. So far the installation is for 15,000 kva., of which one-half is being used, but the plant will be doubled shortly to 30,000 kva. Now 13 or 14 sections of 3500 to 4000 amperes at 125 volts are being run. In the transformer-house there is a set of storage-batteries to operate the switches and also automatically to supply light to the electrical plant in

case of a break in the transmission-line. In the adjacent generator-room, 2300 volts is taken from the West Kootenay Power Co., the alternating current being converted into direct current by Westinghouse and General Electric generators of 500 kw. each, two generators in a set. Seven sets are in place. They deliver current at 125 volts. The saving of labor is noticeable in these direct-current installations: one man per shift of 8 hours, with another on day-shift to attend to repairs. Each unit is distinct, each motor and each generator being under separate control. The visitor is impressed by the quantity of copper used in these plants, especially in the form of buss-bars. The bright copper looks handsome; it is lacquered to prevent oxidation. The noise of the generators is due to the indrawing of the air for cooling, as explained to me by H. E. Large, representative of the General Electric Co. Seven generators at full load will give out 1200 hp. in heat-loss. This cannot be avoided; it is inherent in all electrical apparatus as used today. The temperature of the room was 114° F., when it was 92° outside, owing to the heat thus generated.

All the power-conductors are run underground in fibre conduits. The direct-current generators are provided with the commutating poles introduced eight or nine years ago. The equipment was supplied by the Canadian Westinghouse company at Hamilton and the Canadian General Electric at Peterboro, both of these manufactories being in Ontario. The power company sells electricity to the smelting company at the rate of $\frac{1}{2}$ cent per kw.-hour, which is equivalent to \$20 per hp.-year. At a consumption of 2.2 kw.-hours per pound of spelter, the power consumed in the process of electrolytic extraction represents a cost of 0.73c. per pound of metal.

The supply of cheap lead is a noteworthy factor at Trail. A lot of lead piping has to be used in making changes of one kind or another. The company uses its own lead, sending the scrap back to the refinery, so that none is wasted.

The equipment at Trail includes four Cottrell plants, which receive the waste-gases and dust from the lead blast-furnaces, the copper converters, the lead and zinc roasters, the D-L machine and the II & II pots. The Cottrell apparatus consists of steel tubes, 12 in. diam., in each of which hangs an iron chain charged with 80,000 volts. The effect of the electric current is to compel the deposition of the dust on the sides of the tube. As the dust adheres, it is loosened by blows of a hammer on the outside of the tubes. For those of less than 12-in. diameter, the speed of the furnace-gases must not exceed 3.6 ft. per second in order to ensure effective condensation of the fume. The lead blast-furnaces alone give about 160,000 cu. ft. of gas per minute. The sublimate is discharged into a hopper at the bottom of the tubes and is moved thence automatically by hoes, drags, or spiral conveyors to steel-plate cylindrical receivers, where it burns without the addition of any fuel. The fine sulphur, antimony, and carbon (from the coke) in the sublimate of fume all supply fuel sufficient to form an agglomerate suitable for blast-furnace smelting.

New Decrees in Mexico

During the last few months there have been issued several decrees by Carranza. These may be grouped under three main headings:

I. ACQUISITION OF NEW TITLES. In the case of all new denouncements, before title can be obtained it is necessary for the denouncer to sign a statement submitting himself to the same regulations as would apply to a national, in other words, to renounce his right to apply to his home government for redress should occasion for same arise.

Under normal conditions this law does not seem out of place, but in revolutionary times where revolutionists

collection of claims under one denouncement. Most large properties consist of several *fundos mineros*, and the decree is not clear whether each of these has to be worked or whether it be sufficient that a company operate its property as a whole. Technically, each *fundo minero* separately has to be worked, but it is inconceivable that this can be the meaning of the law.

II. PAYMENT OF WAGES. On October 23, 1916, a decree was issued requiring that all wages be paid on a basis of Mexican gold. A few days later this was interpreted by the Department of Fomento to the effect that the basis of wages should be that existing in 1912, but with the modification that an employee getting \$1.50 or more per day should be paid 50% of 1912 wages and one getting \$1.50 or less should be paid 60%. The rate

MEXICANS SORTING AND SACKING ORE AT EL ORO.

or the Government may seize property and work it for their own account, it would work a great hardship.

II. RETENTION OF TITLES. According to the old law in Mexico, title to mining property (*fundo minero*), was retained so long as taxes were paid. Now, according to a decree of September 11, to retain title all properties are required to commence operations before November 14, 1916, and, furthermore, they are subject to forfeiture should they desist operation for two consecutive months or a total of three months in one year.

On November 13, the operation of this law was postponed by another decree, for three months. Unless a further change is made, then, all properties in Mexico will have to be working by February 14, 1917. There are some districts in Mexico which are inaccessible owing to depredations of bandits; in such cases it is supposed that a special dispensation will be granted.

A technicality exists in this decree in that it states that all *fundos mineros* shall be obliged to work within a certain date, etc. Every mining property may consist of one or more *fundos mineros*, a *fundo minero* being a

of exchange on which these wages have to be paid is issued every ten days by the Department of Hacienda. This has received further modifications, the principal being that the Governor of each State shall decide for his particular State what basis of wages shall be paid. In Jalisco the Governor has decreed that 60% of wages shall be paid (giving another rate of exchange different from the Federal rate), except in the case of miners and farm-laborers, who shall receive the same wage as in 1912 without any reduction. Further dispositions have been made or arranged, whereby part of the money should be paid in silver or gold and part in paper, except in the case of mines, which have been ordered by the Governor to pay all wages in silver, though without any decree to this effect.

The net result of all these decrees and interpretations is that paper money no longer has any value in Mexico nor is it used, except in a few cases, such as for second-class fares on railroads. The last rate of exchange given by the Ministerio de Hacienda is 100 pesos paper for one peso Mexican gold.

Text of the Minerals Separation v. Hyde Decision

SUPREME COURT OF THE UNITED STATES

No. 46.—OCTOBER TERM, 1916.

Minerals Separation, Limited,
and Minerals Separation
American Syndicate, Lim-
ited,

vs.

James M. Hyde.

Certiorari to the United
States Circuit Court
of Appeals, Ninth
Circuit.

[December 11, 1916.]

Mr. Justice CLARKE delivered the opinion of the Court.

In this suit the complainants, the first named as the owner and the other as general licensee, claim an infringement of United States letters patent No. 835120, issued on the 6th day of November 1906, to Henry Livingstone Sulman, Hugh Fitzalis Kirkpatrick-Picard and John Ballot. The usual injunction, accounting and damages are prayed for. The District Court sustained the patent as to claims numbered 1, 2, 3, 5, 6, 7, 9, 10, 11 and 12; found that the defendant had infringed each of these claims, and granted the prayer of the petition. The Circuit Court of Appeals for the Ninth Circuit reversed the decree of the District Court and remanded the case with instructions to dismiss the bill. The case is here on writ of certiorari to review that decision.

As stated in the specification, the claimed discovery of the patent in the suit relates "to improvements in the process for the concentration of ores, the object being to separate metalliferous matter from gangue by means of oils, fatty acids, or other substances which have a preferential affinity for such metalliferous matter over gangue."

The answer denies all of the allegations of the bill and avers that in twenty-five designated United States and five British patents the process described in suit was "fully and clearly described and claimed," and it also avers that the claimed discovery was invented, known and used by many persons long prior to the time when the application was made for the patent in suit. Notwithstanding this elaboration of denial counsel for the defendant in the summarized conclusion to their brief rely upon only five of the many patents referred to as showing that the patent in suit was anticipated and is therefore invalid for want of novelty and invention, viz: Everson (1886), Froment (Italy, 1902; Great Britain, 1903); Glagner (1903), Schwartz (applied for April 19, 1905, issued December 19, 1905), and Kirby (applied for October 17, 1903, issued December 18, 1906). And

the defendant, a man obviously experienced in the subject, says that, in his opinion, the whole basis of flotation concentration was disclosed in the Everson United States patent No. 348157 and in the Froment British patent.

It is clear that in the prior art, as it is developed in this record, it was well known that oil and oily substances had a selective affinity or attraction for, and would unite mechanically with, the minute particles of metal and metallic compounds found in crushed or powdered ores, but would not so unite with the quartz, or rocky non-metallic material, called "gangue." Haynes British patent (1860), and United States patents, Everson (1885), Robson (1897) and Elmore (1901). It was also well known that this selective property of oils and oily substances was increased when applied to some ores by the addition of a small amount of acid to the ore and water used in process of concentration. United States patents, Everson (1885), Elmore (1901), and Cattermole (1904).

Prior to the date of the patent in suit a number of patents had been granted in this and other countries for processes aiming to make practical use of this property of oil and of oil mixed with acid in the treatment of ores, all of which, speaking broadly, consisted in mixing finely crushed or powdered ore with water and oil, sometimes with acid added, and then in variously treating the mass—"the pulp"—thus formed so as to separate the oil, when it became impregnated or loaded with the metal and metal-bearing particles, from the valueless gangue. From the resulting concentrate the metals were recovered in various ways.

The processes, of this general character, described in the prior patents may be roughly divided into two classes. The process in the patents of the first class is called in the record the "Surface Flotation Process" and it depends for its usefulness on the oil used being sufficient to collect and hold in mechanical suspension the small particles of metal and metalliferous compounds and by its buoyancy to carry them to the surface of the mixture of ore, water and oil, thus making it possible, by methods familiar to persons skilled in the art, to float off the concentrate thus obtained into any desired receptacle. The waste material, or gangue, not being affected by the oil and being heavier than water sinks to the bottom of the containing vessel and may be disposed of as desired.

The process of the other class, called in the record the "Metal Sinking Process," reverses the action of the Surface Flotation Process and is illustrated by the Cattermole U. S. patent, No. 777273, in which oil is used to the extent of 1% to 6% to 10% of the weight of the

metalliferous mineral matter, depending on the character of the ore, for the purpose of agglomerating the oil-coated concentrate into granules heavier than water, so that they will sink to the bottom of the containing vessel, permitting the gangue to be carried away by an upward flowing stream of water.

The process of the patent in suit, as described and practiced, consists in the use of an amount of oil which is "critical," and minute as compared with the amount used in prior processes "amounting to a fraction of one per cent on the ore," and in so impregnating with air the mass of ore and water used, by agitation—"by beating air into the mass"—as to cause to rise to the surface of the mass, or pulp, a froth, peculiarly coherent and persistent in character, which is composed of air bubbles with only a trace of oil in them, which carry in mechanical suspension a very high percentage of the metal and metalliferous particles of ore which were contained in the mass of crushed ore subjected to treatment. This froth can be removed and the metal recovered by processes with which the patent is not concerned.

It is obvious that the process of the patent in suit, as we have described it, is not of the Metal Sinking class, and while it may, in terms, be described as a Surface Flotation Process, yet it differs so essentially from all prior processes in its character, in its simplicity of operation and in the resulting concentration, that we are persuaded that it constitutes a new and patentable discovery.

The prior processes which we have described required the use of so much oil that they were too expensive to be used on lean ores, to which they were intended to have their chief application, and the efforts of investigators for several years prior to the discovery of the process in suit had been directed to the search for a means or method of reducing the amount of oil used, and it is clear from the record that approach was being made, slowly, but more and more nearly to the result which was reached by the patentees of the process in suit in March, 1905. The Froment Great Britain patent (1903) and the Kirby United States patent (applied for in 1903 and granted in 1906) are especially suggestive of the advance which was being made toward the desired result, but the Froment process was little more than a laboratory experiment and has never proved of value in practice, and the Kirby process, though approaching in some respects more nearly to the end attained by the process of the patent in suit, found its preferred application in the use of an amount of oil solution equal to one-fourth to three-fourths in weight of the ore treated, which was prohibitive in cost.

Into this field of investigation at this stage of its development came the patentees of the patent in suit. They were experienced metallurgists of London, of inventive genius and with financial resources, and they entered upon an investigation of the processes of oil concentration of ores which was continued through several years, and consisted of a very extended series of experiments in which the quantities of oil, of water and of

acid used and the extent and character of the agitation of the mass under treatment resorted to, were varied to an almost unparalleled extent as to each factor and the results were carefully tabulated and interpreted. It was while pursuing a comprehensive investigation of this character, having, as the evidence shows, the special purpose in mind at the time to trace the effect on the results of the process of a reduction to the vanishing point of the quantity of oil used, that the discovery embodied in the patent in suit was made. The experimenters were working on the Cattermole "Metal Sinking Process" as a basis when it was discovered that the granulation on which the process depended practically ceased when the oleic acid (oil) was reduced to about five per cent "on the ore." It was observed, however, that, as the amount of oleic acid was further reduced and the granulation diminished, there was an increase in the amount of "float froth," which collected on the surface of the mass and that the production of this froth reached its maximum when about one per cent or slightly less "on the ore" of oleic acid was used. This froth, on collection, was found to consist of air bubbles modified by the presence of the minute amount of oil used and holding in mechanical suspension between 70% and 80% of the total mineral content of the mass treated. It was promptly recognized by the patentees that this froth was not due to the liberation of gas in the mass treated by the action of the dilute acid used, and its formation was at once attributed in large part to the presence of the air introduced into the mixture by the agitation which had been resorted to to mix the oil with the particles of crushed ore, which air, in bubbles, attached itself to the mineral particles, slightly coated as they were with what was necessarily an infinitesimal amount of oil, and floated them to the surface. The extent of the agitation of the mass had been increased as the experiments proceeded until the "series of Gabbett mixers, fitted with the usual baffles, were speeded at from 1,000 to 1,100 revolutions per minute."

A careful consideration of the record in this case convinces us that the facts with respect to the process of the patent in suit are not overstated by the plaintiffs' witness, Adolph Liebmann, an expert of learning and experience, when he says in substance:

"The present invention differs essentially from all previous results. It is true that oil is one of the substances used but it is used in quantities much smaller than was ever heard of, and it produces a result never obtained, before. The minerals are obtained in a froth of a peculiar character, consisting of air bubbles which in their covering film have the minerals embedded in such manner that they form a complete surface all over the bubbles. A remarkable fact with regard to this froth is that, although the very light and easily destructible air bubbles are covered with a heavy mineral, yet the froth is stable and utterly different from any froth known before, being so permanent in character that I have personally seen it stand for twenty-four hours without any change having taken place. The simplicity

of the operation, as compared with the prior attempts, is startling. All that has to be done is to add a minute quantity of oil to the pulp to which acid may or may not be added, agitate for from two and one-half to ten minutes and then after a few seconds collect from the surface the froth which will contain a large percentage of the minerals present in the ore."

It is not necessary for us to go into a detailed examination of the process in suit to distinguish it from the processes of the patents relied on as anticipations, convinced as we are that the small amount of oil used makes it impossible that the lifting force which separates the metallic particles of the pulp from the other substances of it is not to be found principally in the buoyancy of the oil used, as was the case in prior processes, but that this force is to be found, chiefly, in the buoyancy of the air bubbles introduced into the mixture by an agitation greater than and different from that which had been resorted to before and that this advance on the prior art and the resulting froth concentrate so different from the product of other processes make of it a patentable discovery as new and original as it has proved useful and economical. It results without more discussion, that we fully agree with the decision of the House of Lords, arrived at upon a different record and with different witnesses, but when dealing with the equivalent of the patent in suit, in *Minerals Separation, Limited, v. British Air Concentration Syndicate, Limited*, 27 R. P. C. 33. In this decision Lord Shaw, speaking for the court and distinguishing the process there in suit especially from the Elmore oil flotation process which had gone before but which was typical of the then prior art said: "They (the patentees of the Agitation Froth Process of the patent in suit) are not promoting a method of separation which had before been described, but they are engaged upon a new method of separation. Instead of relying upon the lesser specific gravity of oil in bulk they rely upon the production of a froth by means of the minute quantities of oil reaching the minute particles of metal, but forms a multitude of air cells, the buoyancy of which air cells, forming around single particles of the metal, floats them to the surface of the liquid."

And Lord Atkinson said: "In their process this mysterious affinity of oil for the metallic particles of the ore is availed of, yet the oil is used in such relatively infinitesimal quantities, that the metallic particles are only coated with a thin film of it, and the lifting force is found not in the natural buoyancy of the mass of added oil, but in the buoyancy of air bubbles, which, introduced into the mixture by the more or less violent agitation of it, envelop or become attached to, the thinly oiled metallic particles, and raise them to the surface, where they are maintained by what is styled the surface tension of the water."

The record shows not only that the process in suit was promptly considered by the patentees as an original and important discovery, but that it was immediately generally accepted as so great an advance over any process

known before that, without puffing or other business exploitation, it promptly came into extensive use for the concentration of ores in most, if not all, of the principal mining countries of the world, notably in the United States, Australia, Sweden, Chile and Cuba, and that, because of its economy and simplicity, it has largely replaced all earlier processes. This, of itself, is persuasive evidence of that invention which it is the purpose of the patent laws to reward and protect. *Diamond Rubber Co. v. Consolidated Tire Co.*, 220 U. S. 428; *Carnegie Steel Co. v. Cambria Iron Co.*, 185, U. S. 403, 429, 430; *The Barbed Wire Patent*, 143 U. S. 275; *Smith v. Good-year Dental Vulcanite Co.*, 93 U. S. 486.

The claim that the patentees of the patent in suit are not the original discoverers of the process patented because an employee of theirs happened to make the analyses and observations which resulted immediately in the discovery, cannot be allowed. The record shows very clearly that the patentees planned the experiments in progress when the discovery was made; that they directed the investigations day by day, conducting them in large part personally and that they interpreted the results. *Agawam Company v. Jordan*, 7 Wall. 583-603, rules this claim against the defendant.

Equally untenable is the claim that the patent is invalid for the reason that the evidence shows that when different ores are treated preliminary tests must be made to determine the amount of oil and the extent of agitation necessary in order to obtain the best results. Such variation of treatment must be within the scope of the claims, and the certainty which the law requires in patents is not greater than is reasonable, having regard to their subject matter. The composition of ores varies infinitely, each one presenting its special problem, and it is obviously impossible to specify in a patent the precise treatment which would be most successful and economical in each case. The process is one for dealing with a large class of substances and the range of treatment within the terms of the claims, while leaving something to the skill of persons applying the invention, is clearly sufficiently definite to guide those skilled in the art to its successful application, as the evidence abundantly shows. This satisfies the law. *Mowry v. Whitney*, 14 Wall. 620; *Ives v. Hamilton*, 92 U. S. 426, and *Carnegie Steel Co. v. Cambria Iron Co.*, 185 U. S. 403, 436, 437.

The evidence of infringement is clear.

While we thus find in favor of the validity of the patent, we cannot agree with the District Court in regarding it valid as to all of the claims in suit. As we have pointed out in this opinion there were many investigators at work in this field to which the process in suit relates when the patentees came into it, and it was while engaged in study of prior kindred processes that their discovery was made. While the evidence in the case makes it clear that they discovered the final step which converted experiment into solution, "turned failure into success," (*The Barbed Wire Patent*, 143 U. S. 275), yet the investigations preceding were so informing that this final step was not a long one and the patent must be con-

fined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as "critical proportions" "amounting to a fraction of one per cent on the ore," and therefore the decree of this court will be that the patent is valid as to claims No. 1, 2, 3, 5, 6, 7 and 12, and that the defendant infringed these claims, but that it is invalid as to claims 9, 10 and 11. Claims No. 4, 8 and 13 were

not considered in the decrees of the two lower courts and are not in issue in this proceeding.

The decision of the Circuit Court of Appeals will be reversed, and the decision of the District Court modified to conform to the conclusions expressed in this opinion, will be affirmed.

A true copy.

Test: Clerk Supreme Court, U. S.

Accidents in California

The Industrial Accident Commission of California reports that for the year ended June 30, 1916, there were 533 deaths, 1264 permanent injuries, and 65,741 temporary injuries. There was a reduction of 158 deaths compared with 1914-'15. There were also 28 less permanent injuries, but 5500 more temporary injuries. The latter is accounted for by the growth of industry. There are nearly 1,000,000 wage-earners in the State. The compensation paid to injured workers or their dependents for 67,538 injuries was \$1,150,504. The medical cost was \$852,202. The wage-loss created by industrial injury was close to \$18,250,000. Over 90% of the compensable injuries are not disputed. The average number of days between medical examinations and decisions was 29.31 days. More and more as time goes on it has been found advantageous to rate permanent injuries on the loss of earning power, based on the nature of injury or disfigurement, the occupation, and the age.

The income of the State Compensation Insurance Fund to June 30, 1916, had reached \$1,837,761. Expenditures and reserves amounted to \$1,161,315. Refunds to policyholders have been paid to the extent of \$134,382, leaving a net surplus of admitted assets over liabilities of \$242,063. The dividends declared have amounted to 15% of the premiums earned during the years 1914 and 1915. The total will probably exceed \$170,000 when pay-rolls of all insured employers have been ascertained. The actual refunds do not constitute the entire saving to patrons, but really represent a saving in operating cost only. The total average expense-ratio is 14.17%, or less than half that of insurance corporations.

The general safety orders for California's industries became effective on January 1, 1916. The mine-safety rules became effective on the same date. These were compiled by a committee of operators and miners, in conjunction with the mining engineer who heads the mining department under the co-operative agreement in effect between the U. S. Bureau of Mines and the Industrial Accident Commission. There was started a safety campaign among those engaged in California's mining industry. A total of 355 mines, quarries, and dredges was inspected. Training in first aid to the injured was given to 711 miners. The interest of miners was enlisted in safety by the formation of the Miner's Safety Bear Club. More than 5000 miners are on the membership roll. This club is unique in that it has no dues and each member receives a safety-bear button and safety literature contributed by the State through the Commission.

Court Decisions on Compensation

The most important decision of the Supreme Court was rendered in the case of the Western Indemnity Co. v. Industrial Accident Commission of California (151 Pac. 398), when a divided Court found full sanction for the statute in the police power and in the right and power of the Legislature to classify occupations for the purpose of this kind of legislation.

In the case of the Western Metal Supply Co. v. Industrial Accident Commission (51 Cal. Dec. 447) a divided Court upheld the validity of the extension of the Act by the Legislature to cover death benefits to dependents of workmen fatally injured, and upheld its further extension for the benefit of alien dependents.

The Supreme Court leans strongly toward the position that the Industrial Accident Commission is "in legal effect" a court, because it is invested with many of the formal functions of a judicial tribunal. It is asserted by the Commission that compensation, insurance, and safety are so intimately related and interwoven as parts of an adequate compensation system, as to require intimate knowledge and close contact with all three departments.

Wilful misconduct has been broadly constructed in the Commission's decisions. The Courts have taken a narrower view and have annulled several awards.

In the case of the North Alaska Salmon Co. v. Pillsbury *et al.* (51 Cal. Dec. 473) the Commission's award was affirmed that the compensation statute extends to cover injuries and deaths suffered by employees without the physical boundaries of the State, where the contract of hire is made within the State and the employee is a resident of the State. A petition for re-hearing was granted.

BLAST-HOLE MACHINES, as they are called, are drilling-machines of the Keystone type, used to drill holes 6 in. diameter and 35 to 10 ft. deep for the purpose of blasting down a large amount of ore or waste in advance of the steam-shovels. They are used in all of the great excavations of the disseminated-copper deposits. The holes are usually drilled about 20 ft. back from the edge of the terrace, or face, on which work is progressing. Several holes are drilled at intervals of 20 or 25 ft. and these are "sprung" several times and then charged heavily for the final blast. Where conditions are favorable thousands of tons of rock, or ore, are thrown down in a single series of blasts prepared in this manner.

Manganese in West-Central Arkansas

By Garnett A. Joslin

Knowledge of the presence of manganese in the Ouachita mountains of west-central Arkansas antedates the Civil War, yet, until the present summer, there has been no active interest in the deposits. Some desultory prospecting was done years ago, under the impression that the psilomelane was an ore of gold, but the holes have long since caved and the prospectors vanished. Later, when the ore was identified, the demand for manganese offered no incentive for prospecting a field so inaccessible. Railroads were far away and the few roads were bad. A report by Penrose,* published by the Geological Survey of Arkansas in 1890, and later the comments of Harder,† in a bulletin of the U. S. Geological Survey, offered little encouragement to the prospector. Now, with railroads nearer and wagon-roads in better condition, the higher price for the ore has stimulated prospecting and it is probable the present year will determine whether the district can profitably produce manganese ore.

The manganese belt of west-central Arkansas extends from Polk county, on the west, in an easterly direction to Pulaski county on the east. The part of the belt to be described consists of those portions of Pike, Montgomery, and Polk counties that lie in the Ouachita mountains. The Ouachita mountains extend south of the Arkansas river in an east-west chain, and form a prominent feature of the topography. Structurally, the system is an anticlinorium characterized by many sharp ridges that rise 500 to 1000 ft. above the intervening valleys, or to altitudes of 1500 to 2000 ft. above sea-level. These anticlinal ridges are formed of steeply-dipping beds, are roughly parallel, and trend east-west; the anticlinorium having been formed by thrust-pressure from the north and south. The rocks are sedimentary, comprising sandstone, chert, shale, and novaculite. Erosion has accentuated the steep slope of the ridges by cutting into the softer sandstones and shales, forming streambeds and leaving sharp crests of the novaculite and the harder sandstone. Water-gaps cut the ridges in a north-south direction at frequent intervals.

The rocks of economic interest are the shale and the novaculite. Novaculite (razor-stone) is a sedimentary rock resembling dense fine-grained quartzite, and was long thought to be quartzite, having been described by Kemp as "a silicious ooze." Whether this term suggests the correct genesis is open to question, but as a lever to dislodge the name "quartzite" from the mind it is admirable. Manganese ore occurs in the lower part of the novaculite bed and in its upper portion with the overlying shale. It forms discontinuous lenses, which follow bedding-planes, frequently widening to fill joint-cracks and form local segregations at the junction of bedding-

plane and joint-crack. It also occurs as a manganese cement in a novaculite-breccia. In general the ore is a blue-black psilomelane, commonly botryoidal, containing occasional pockets of pyrolusite in soft earthy masses. In intimate association with the manganese are ores of iron that vary from black botryoidal hydrated oxides to the familiar 'brown ores.' They occur in the same lens, either with the manganese or wholly displacing it, and in separate bedding-planes. In prospecting the iron is considered a good lead to manganese.

Successive outcrops of an ore-bearing horizon in the novaculite may be traced for miles. It is this general east-west continuity, together with the frequent repetition of the outcrops in a north-south direction—due to the close folding that causes the beds to rise and plunge alternately—that causes prospectors to believe in a system of parallel 'fissure-veins,' while the native mountaineers hold that there are "mountains of ore."

In this connection, and in speculating on the depth to which the manganese may go, the origin of the ore should be considered. Such evidence as has been gathered points to a theory similar to that advanced by Harder‡ for the origin of the manganese ore of the Appalachian region, which appears to apply to that of the Ouachita mountains. The rocks from which the novaculite was derived contained manganese minerals that were deposited with the sediments. After emergence from the sea, erosion began, the manganese was dissolved, precipitated and concentrated by percolating waters along favorable bedding-planes and joint-cracks in what are now the lower manganese horizon and the upper portion of the novaculite beds. If this theory is correct, it follows that there will be no marked persistence of ore below the ground-water level.

Methods of prospecting so far developed are both good and bad. Individuals and groups of men who have staked claims, or own land upon which manganese occurs, men who have little money to spare and must therefore make their work pay for itself, are forced to follow that golden rule: "Follow the ore." Several shafts now being sunk, in the belief that the richer ore is deeper may throw some light upon the depth to which profitable ore may be expected. In general the prospectors and miners who cannot afford to pay for the advice of a mining engineer are following the usual methods. In one instance a cross-cut adit is being driven to cut a lode that outcrops on the hillside several hundred feet above the 'tunnel' mouth, in the belief that the lode is vertical. A brief study of the structure would have shown that the direction of dip of the ore-horizon at this place is the same as the line of the adit. The lure of the cheap operating cost of the cross-adit still hovers over undeveloped prospects. With a little more attention to geological

*R. A. F. Penrose, Jr., Ark. Geol. Surv., vol. 1, 1893.

†Edmund Cecil Harder, U. S. G. S. Bull. 427, 1910.

‡U. S. G. S. Bull. 427, pp. 99-100.

structure and some serious speculation over the origin of the ore, more would be learned about the deposits.

Harder in his report discouraged prospecting when he stated that widths of over a foot were rare. At the present time there are several prospects that show a width of three feet and over of solid psilomelane. Several carloads of ore have been shipped. It is reported that this ore gave returns of 50 to 60% manganese. This seems to be the average for the sorted ore of the region. Silica sometimes mounts to 8% and the phosphorous content is usually about 0.2%. There is a fair chance that somewhere in this region a profitable mine will be developed.

Mining conditions are good. Water is abundant and the hills are covered with pine and oak. The climate is favorable. It is estimated that roads suitable for motor-truck haulage can be built connecting with railroad-points at a moderate cost per mile. Labor is cheap, the prevailing wage being \$1.50 per day and board, but as might be expected, it is inexperienced and erratic. The mountaineer is illiterate and none too fond of work. He is prone to light a ten-minute fuse and then run a quarter of a mile at top speed. He has much respect for dynamite and very little for 'moonshine.' So far the supply of men has been ample for all operators and the 'cost of firing' may be considered as negligible.

Nitrates in the United States

Nitrate deposits in many parts of this country have been examined during the last two years by the U. S. Geological Survey. The importance of finding a natural supply of nitrates within our own borders, which might serve our needs in case of war, has given incentive to this work, and has directed widespread public attention to the subject.

Prospectors in many places have raised great hopes by finding good surface-showings of these salts, but investigation has seemed to force the acceptance of a general adverse judgment as to their value—a judgment that has been adopted with the greatest reluctance by all concerned. Incidentally, advantage seems to have been taken of the situation to promote certain share-selling enterprises, even after the evidence as to the worthlessness of the deposits became sufficient to satisfy any competent judge, so that one is forced to question either the good faith of the promoters or their practical judgment. As a result of careful study of these deposits, and particularly of evidence gathered on recent visits to prospects in different parts of the country, Hoyt S. Gale, a geologist of the Survey, has submitted the following general summary, which is commended to the consideration of those tempted to invest their money in such enterprises.

Fine specimens of practically pure nitrate of soda and nitrate of potash—saltpeter—have been found in many parts of the country, and careful investigation of specimens and localities seems to warrant some definite conclusions as to the practical value of these deposits, especially to those who are invited to spend their money in investigations like those the Survey has already made. The nitrate salts occur as crusts or films on the faces of ledges; as seams—most of them thin, though some are fairly thick—in crevices of shattered rock; and as deposits filling spaces in porous rocks at and near the surface or extending to a depth of several feet. They are naturally preserved in recesses in the rock ledges, where they are sheltered from the dissolving action of rain, snow-water, or even mist. They are found in lava ledges, in beds of volcanic tuff or ash, and in limestone and sandstone. Their existence or preservation is apparently

dependent rather on the shattered or porous nature of the rock than on its kind or composition. These deposits, which have been referred to as cave or ledge deposits, are of essentially the same type wherever found, although they vary considerably in details of occurrence. The incrustations are found not only on the faces and fractures of ledges of solid rock, but some of them form layers or cementing constituents in the loose soil and rock-breccia at the bases of cliffs, or lie in places protected from the weather. Some samples obtained from both these sources are rich in nitrate salts, and analyses of such materials will bear little significant relation to the actual character or content of the mass of the rock of which the ledge is formed. It appears that the deposits are surficial—that is, they do not extend far into the mass of the rock—and the nitrate salt found is insignificant in amount. Nitrates are found in unusually large quantities in some soils and in some clay hills, particularly in southern California. These deposits have been examined by many persons and the general conclusion reached has been unfavorable to the idea of their practical utilization. The nitrate content, although unusually large as compared with the content of ordinary soils, probably does not average over 1 or 2% of the soil or clay, and it is doubtful whether the material could be worked commercially.

Any one who is not convinced by the judgment already reached as to these deposits, and who is determined to devote his time or money to their further exploration, should do so with full knowledge of the evidence already in hand and should not be led into such a venture by more or less misleading representations. The Survey will always be glad to make an examination of any samples submitted.

The Aluminum Ore Co., a subsidiary of the Aluminum Co. of America, of Pittsburgh, has bought 200 acres at Sellers Point, Md., where a plant will be built to manufacture aluminum from bauxite. The capacity of this new plant will be less than the company's plant at East St. Louis, but is so planned that extensions can be made as needed. It will cost about \$1,000,000 and is expected to be ready for operation early in 1918.

Matte Granulation at Herculaneum, Missouri

By S. Paul Lindan and Henry B. Smith

*Three years ago it was decided by the management to granulate the matte produced in the smelter of the St. Joseph Lead Co. at Herculaneum, thereby doing away with a large amount of labor in handling the matte and in subsequent crushing. On March 1, 1915, the granulator was put in operation and up to January 1, 1916, 18,735 tons had been granulated. The four blast-furnaces have a daily output of about 280 tons of pig-lead and 100 tons of matte assaying about 11% lead. It is expected that projected improvements in roasting methods will eliminate more sulphur from the charge, and cut down the matte-fall to about one-half of the present figure.

The blast-furnaces are tapped into movable fore-bearths or settlers, 6 ft. by 4 ft. by 22 in., the slag overflowing into 27-cu. ft. slag-cars that are hauled to the dump by electric locomotives.

Under the present plan of granulating, the matte is tapped into 6-cu. ft. iron ladles. These are transported

*Abstract from paper to be read before the American Institute of Mining Engineers New York meeting, February 1917.

to the granulating-plant by a 5-ton overhead electric traveling-crane, the runway of which extends the full length of the blast-furnace building. A cylindrical container receives the matte from the ladles. This container is a specially designed Traylor copper-converter minus the tuyeres and with a 20-in. opening at one end for the flue and oil-burners. It measures 77 by 120 in. inside, is lined with magnesite brick 9 in. thick and can be tilted by means of a 50-hp. motor. A steel flue 18 in. diameter, leading from one end, conducts any fume to the bag-house. Just under this flue are placed two oil-burners for heating. Generally one is found sufficient to keep the matte in a molten state. The consumption of 18 to 20° B. crude oil is 250 gal. per 24 hr., or 2 to 2½ gal. of oil per ton of matte granulated. Air at 30 lb. pressure is supplied to the burners for atomizing the oil.

The granulation is accomplished by pouring the molten matte through two superimposed flat jets of water shooting horizontally into a concrete tank lined with cast-iron plates. The stream of matte is disintegrated into small shot-like particles before reaching the body of

MATTE GRANULATING PLANT OF THE ST. JOSEPH LEAD CO. AT HERCULANEUM, MISSOURI

water. The stream of molten matte is accurately directed on the jets of water by a so-called pouring-box, the spout of which is 6 in. above and 12 in. in front of the upper nozzle. This box is lined with common brick and the matte is poured directly into it by revolving the container. The pour-holes are slots 2 in. wide by 8 in. high.

A dewatering drag-conveyor removes the granulated particles of matte from the tank. The floor of the tank slopes down to the trough in which the conveyor operates, at an angle of about 30° . It is placed to one side, out of the line of the streams from the nozzles. It elevates the matte over the slag-track and discharges into standard-gauge railroad cars, which are weighed, and their contents sampled and emptied into the roaster-bins. In the end of the concrete tank opposite the nozzles, a V-shaped settling-box takes the overflow water. This box prevents the loss of the coarser slime, while the finer material settles out in a series of settling-tanks, one overflowing into the other. An excelsior filter finally clears the water before it enters the circulating pond. There are two series of settling-tanks, one in use while the other is being cleaned out.

The matte in the cylindrical container is kept fluid by one or both of the two oil-burners before mentioned. The burners are placed so that the flame shoots slightly upward in the container. An oxidizing flame is used, though there would be some practical advantages if a reducing flame could be employed. It was found impossible, however, to maintain the required temperature with a reducing flame. If the matte remains in the container too long, an oxidized scum is formed which interferes with the pouring.

The matte is discharged from the barrel container through an opening in the side, 2 by 8 in., provided with a spout delivering into the pouring-box which rests on the concrete wall of the tank directly over the water-nozzles. This pouring-box is made of sheet-iron and is lined with common firebrick; inside dimensions are 18 in. by 18 in. by 3 ft. The matte tends to chill and build up in the box, but a narrow passage about 3 in. wide is easily maintained along the path of the stream. This box in turn discharges through an opening 2 by 8 in., the matte being directed by a cast-iron spout so that it meets the horizontal jets of water at an angle of 70° to 80° . All the matte should be broken up and be pre-chilled before striking the main body of water. As a rule the stream of matte is broken up by striking the upper jet while the lower jet insures further cooling. It was found that if some of the matte missed the jets or if the rate of pouring was too rapid, thus preventing the thorough pre-chilling of the matte, some of the semi-molten particles united again into large lumps, frequently causing explosions in the tank. Likewise, too rapid pouring will promote the formation of large granules up to an inch in diameter, which are detrimental to good roasting. Too slow pouring allows the matte to chill before leaving the pouring box, thereby causing the opening in the spout to freeze gradually. The right speed was obtained after a little experimentation. A stream

of matte as large as $2\frac{1}{2}$ in. diam. where it strikes the jets has been granulated satisfactorily. A hot matte makes a better product for roasting, because it is more uniform and finer. A good product is that of which 75% passes a $\frac{1}{16}$ -in. screen. The average rate of pouring is 3.2 cu. ft. of matte per minute.

The water-jets are delivered through rectangular nozzles, the openings being $\frac{3}{4}$ by $3\frac{1}{4}$ in. with the nozzles 5 in. apart. The supply of water is 100 gal. per min. under a head of 40 ft. The granulating-tank is constructed of concrete, 17 ft. long and $7\frac{1}{2}$ ft. wide, the floor being plated with 1-in. cast-iron plates, at a 30° slope into the conveyor-trough. This degree of slope has been found sufficient to cause the granulated particles to run into this trough. The drag-conveyor is driven by a 10-hp. motor at a speed of 30 ft. per min. and runs in a sectional cast-iron trough 4 in. deep and 15 in. wide. A small amount of water, about 5%, passes over with the matte into the railroad-cars, drainage being assisted by notching the conveyor-flights alternately in the centre and on the ends, thus allowing the entrained water to escape and flow back into the tank. The tail-sprocket wheel and the idler-sprocket wheel are both under water. The shafts of these wheels extend through stuffing boxes in the sides of the tank, to the bearings on the outside.

Some lead settles out of the matte while in the container, about 30 to 60 pigs of 65 lb. each, according to the condition of the furnaces, being poured out daily. In case lead goes over and is granulated with the matte, it manifests itself by a sputtering and popping on the surface of the water. After the matte has been poured down to the lead-level, the operator turns the container backward and pours the lead into a ladle, whence it is molded into pigs.

To prevent metal losses, the fumes are caught by a swinging hood that fits over the charge-opening and connects with the blast-furnace flue leading to the bag-house. The hood may be swung back so as to uncover the charge-opening, when the crane is ready to pour a ladle of matte into the barrel-container.

This installation requires only two men per shift for operation, one to operate the container and one the crane. The forehearth tappers at the furnaces attach the crane-hook to the ladles. Under the old method of handling the matte by hand-pots, the cost was \$7c. per ton, which included hand-breaking. Crushing and screening amounted to 56c. per ton in addition, which brought the total cost to \$1.43 per ton. Granulation costs only 75c. per ton, which makes the total saving of $\$1.43 - 0.75 = \0.68 per ton of matte granulated.

SOME of the large more progressive manufacturers of the East are seriously considering the adoption of the metric system of weights and measures, and to this end enquiry is being made by the Philadelphia Bourse to ascertain to what extent the French system can be readily adopted in catering to the large and rapidly increasing foreign trade.

Counter-Current Decantation

By L. B. Eames

*The recovery of dissolved gold from pulp in cyanide-plants was first accomplished by intermittent decantation. This simple process consists in mixing with the pulp, containing the metal in solution, a solution of lower gold-content, settling the mixture in a tank, and decanting the clear supernatant liquor. The thick pulp remaining in the tank is pumped to a second tank, together with more barren solution, and again settled and decanted. After several repetitions of this operation, the value is so far reduced that further washing is not profitable. Gold extraction by this process is high, but the plant required is extensive, labor cost is high, and the amount of solution to be precipitated is excessive.

In 1901, John Randall employed the same principle in cones, instead of flat-bottomed tanks, which operated continuously, discharging a regular stream of thickened pulp. These cones were operated in series, the thick under-flow of the first one forming, with a stream of diluting solution, the feed to the second cone of the series. Barren solution was added to the tank immediately preceding the discharge-tank and, after being slightly enriched by the low-grade pulp in this tank, overflowed to form a diluting solution again for the richer feed entering the third tank from the end of the series, and so on back to the richest tank of the series. Clear water was used for the wash in the final tank. This is the principle on which all successful counter-current decantation plants operate at the present time, but Randall's plant was not successful because of mechanical difficulties in getting a continuous thick discharge from his cone-tanks.

In 1910, two decantation plants were built making use of flow-sheets similar to that used by Randall 9 years before, but substituting Dorr thickeners for the cones. One of these was at Moerito in Sinaloa, Mexico, and was installed under the direction of C. Dupre Smith; while the other was designed by J. V. N. Dorr, assisted by the writer, for the Vulture Mines Co. of Wickenburg, Arizona. While perhaps not perfect at first, both of these pioneer plants were so successful as to encourage further installations, which have increased considerably during the past three years.

The accompanying sketch is a simple yet typical flow-sheet of the C.C.D. system. It is assumed that crushing is done in cyanide solution, the overflow from the tank T_2 being used for the crushing-solution. This solution leaves the grinding-circuit with the ground pulp and enters T_1 , and that part which does not pass to the agitators with the pulp overflows T_1 , and goes to precipitation. After depositing its gold-content, it is used to dilute the underflow of T_1 as it enters T_2 . The overflow of T_2 is also mixed into the feed to T_3 . The overflow of T_3 mixes with the underflow of T_2 to form the feed

to T_4 , and so forth, as indicated in the flow-sheet. At each succeeding mixture the solution meets a pulp of higher dissolved metal-content than itself, and is enriched while the pulp is correspondingly impoverished. The pulp at each step approaches the discharge-end of the mill while the solution goes to the feed end—hence counter-current decantation.

The principal factors that may affect the efficiency of the process are: (1) grade of ore; (2) ratio of solution precipitated to ore treated; (3) thickness at which pulp can be discharged; (4) cost of chemicals; (5) rapidity of dissolving, and the place in the circuit where it takes place; and (6) efficiency of precipitation.

Since the process is one involving volumes and dilutions, it is possible to calculate accurately what distribution of metal-content should take place under any given set of conditions. As far as possible, each one of the above variables has been mathematically considered independently of the rest and the results have been plotted. [In the PRESS of August 28, 1915, these calculations were given in full, when the Rochester Mines Co.'s mill was described.—EDITOR.]

Any considerable dissolving during decantation will

FLOW-SHEET OF C.C.D. PLANT.

be indicated by a difference in the assay-value of the solution in the under-flow of the tanks as compared with the over-flowing solution. In practice there is always more gold per ton in the under-flow solution than in the over-flow of any given tank, but in the ores of Porcupine district, Ontario, this difference is very small. Other causes may, and no doubt do, tend to produce this difference between the over-flow and the under-flowing solution. Adsorption is probably the most important and perhaps the least understood of these. In the case of Porcupine ores this phenomenon is of small importance, as the ore is composed of crystalline schist and quartz, and there is little tendency for the ore to flocculate under the influence of the solutions used. The gold and silver ores of the Western States are in many cases in eruptive rocks; these ores usually flocculate in solution, and in doing so seem to entrap a portion of the metal in solution. At any rate there is a much more noticeable difference in the assays of tank effluents in the treatment of these ores. This has in some cases been blamed on faulty mixing of the products fed to the tank.

Proper precipitation is essential in decantation, as the amount of dissolved gold lost is in proportion to the value of the barren solution used.

At the Hollinger mill at Porcupine, the decantation plant at present consists of five rows of 40-ft. tanks, four tanks to a row, forming a plant of five units. The

*Abstract from paper prepared for New York meeting of American Institute of Mining Engineers.

tanks are arranged with a difference in elevation of 2 ft. 6 in. between steps, with the final tanks of the series the highest, so that all solutions pass through and out of the plant to precipitation. The diaphragm-pumps used were designed by the company's staff, and have been reliable and economical. They are all three-throw or triplex pumps, so that in spite of the large tonnage handled, the duty on each diaphragm is light. The barren solution and water-wash added to each row are measured by separate float-reading weir-boxes assuring uniform results from the various units. Only one man is necessary for each shift. Power consumed by each tank is under one horse-power, while each pump uses about the

same. The cost of decanting is 2.09c. per ton. The recovery is almost the theoretical maximum. The following table gives results covering a period during which 38,885 tons of \$8.92 ore was treated:

Ratio of ore to solution precipitated.....	100 to 285
Solution precipitated, tons.....	110,604
Strength of cyanide used.....	0.9 lb. per ton, or 0.0045%
Cyanide added per ton of ore, pounds.....	0.46
Difference between pulp-feed and pulp-discharge for first tank after agitators, cents.....	25
Average moisture in tailing, per cent.....	45
Average value of barren solution, cents.....	3.2
Dissolved gold per ton of solution discharged, cents.....	11.71
Dissolved gold per ton of ore discharged, cents.....	9.57

A Discovery of Celestite

By Willard Mallory

Four miles north-east of Lavic station, on the Santa Fe railroad, in San Bernardino county, California, is a large deposit of celestite, the white outcrops of which are plainly visible from the railroad, which at its nearest point is two and one-half miles south.

These outcrops have been examined by prospectors many times, but only recently has the real character of the mineral in them been determined. The deposit is in a stratified formation with an easterly strike and a steep dip to the south. It lies along the southern base of a mountain composed of Tertiary volcanic rocks and occupies a tilted position in normal relation to this mountain uplift.

This formation has an average width of 100 ft. for a length of 2000 ft. To the east it narrows rapidly in width and finally gives place to a wide zone of banded red and yellow jasper. Westward it plunges under a heavy overburden of sand and drift. Upon both sides is a conformable series of banded red and yellow jasper, that forms the walls of the deposit. The foot-wall jasper is succeeded by the volcanic rocks of the mountain to the north. The hanging-wall jasper is overlain by a black finely crystalline limestone, which continues under the drift-sand of the valley.

All the outcropping rock within the dimensions given is celestite, although the material varies in texture and purity in the different strata. Some is darkly discolored by oxide of manganese, other portions are free from impurities, and in these the ore is finely crystalline, of a sugary texture and yellowish-white. It has a high specific gravity, but is appreciably lighter than barite, for which it has been mistaken. Analysis shows 95% strontium sulphate.

A number of veinlets, two to three inches wide form fibrous crystalline celestite, with the typical pale-blue tinge from which the mineral derives its name. The longer axis of the crystals lies across the course of the veinlets, their length being determined by the width of the latter.

In many instances celestite deposits appear to be the result of precipitation and to have an origin analogous

to that of gypsum, which is associated with them. Gypsum does not occur in this deposit, but jasper, which is often recognized as precipitated silica, is an important associate. Precipitation can with reason be held to ac-

OUTCROP OF CELESTITE NEAR LAVIC, CALIFORNIA.

count for the celestite in this instance but other conditions observed preclude the application of this theory and suggest one wherein circulating hot waters, with strontium compounds and silica in solution, have attacked a sedimentary series along an igneous contact, resulting in extensive replacement of limestone by celestite, and of calcareous and silicious shales by jasper.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

FARTHEST NORTH for a cyanide plant is claimed by the Willow Creek mill on Cook's inlet, Alaska. The latitude is 61° 45' N.

GOLD-BEARING arsenical minerals (mispickel and lollingite) are floated with difficulty at the Tul Mi Chung mill in Korea.

WATER-TIGHT canvas can be made by coating it with a mixture of five parts of coal tar, one part gasoline, and one part japan dryer.

TEMPERATURE of flotation concentrate at the Inspiration Consolidated affects the rate of filtration on Oliver machines, and arrangements have been made to use hot water from condensers.

GRADING in soft material during wet weather, when the working place is likely to become a quagmire, always justifies the laying of tracks and the use of cars, even if both track and cars are of rude construction.

IN 1905 and 1906 the Elmore bulk-oil process was used at the Massey mine, in Ontario, with success, as regards recovery, which was 87%; but the cost of the oil, too much of which was wasted, rendered the operation uneconomical.

DAMPERS placed in ventilation pipes in mines should be made of extra heavy sheet iron or steel or they will be found to be severely bent by concussion due to blasting; the tendency to double up will always be inward, not outward, as may be supposed.

AT OURO PRETO, in Brazil, the *jurupeba*, one of the *solanaceae* and a soap-bearing plant, is used in the Passagem stamp-mill to hasten the settling of fine gold, that is, to prevent the floating of gold. This effect is due to lowering of the surface tension of the water.

THE TRACK-JACK is one of the most useful tools about a mine either on the surface or underground. It is useful not only in adjusting the grade of tracks, but in replacing derailed cars and in numerous other ways. It is easily carried, quick and direct in action, and once employed seems indispensable.

ALASKITE was a name originally applied by J. E. Spurr to aplite that contained a large amount of quartz, much of which was due to the secondary deposition of silica, great quantities of which he found in some parts of Alaska. The term has more recently been extended to include all rocks composed principally of quartz and alkali feldspar.

TITANIUM is a silver-white metal with a specific gravity of 4.5. It occurs most commonly as rutile, titanium di-oxide. Titanium unites with other metals to form alloys; an alloy of titanium and iron is used as a de-oxidizer in the purification of steel. Carbide of titanium is formed at high temperature. This is known commercially as ferro-carbon-titanium, and is made by reducing titaniferous iron ores in an electric furnace.

IMPURITIES most common in magnesite are alumina, silica, lime, and iron. Buyers generally penalize too much of either of the first three, but for some purposes make no objection to the iron unless it occurs in excess of 5%, preferring iron up to 3 or 4% in the raw ore. Silica is permissible up to 5% if the magnesite is to be used for furnace linings. In chromic iron the usual impurities are alumina and ferrous iron, neither of which substances can be detected readily by the eye, though an analysis promptly discloses their presence.

CONCRETE may be placed successfully in freezing weather by heating the rock and sand, and the water used in making the mixture, just before it is placed in the forms. In some instances concrete thus placed has been protected from freezing by arranging improvised radiators of 2-in. pipes at the sides of the concrete mass, turning steam into the pipes, and covering the whole with tarpaulins. In other cases, a constant flow of hot water has been discharged on the concrete, which permitted the cement to set firmly before freezing should cause it to disintegrate.

STEEL CABLES may be either cut or welded by means of the oxy-acetylene flame, but a broken cable welded by this method would have its usefulness as a hoisting rope largely impaired, if not destroyed, for the reason that the individual wires composing the cable would have their tensile strength diminished by the process of annealing, which could not be avoided. Cables welded by this method might safely be used for standing-ropes when the tension to which they will be subjected never exceeded 50% of the original guaranteed tensile strength, as stated by the manufacturers of the rope.

CAUSTIC SODA is added to ball-mill pulp—containing 35% moisture—at the Tul Mi Chung plant of the Seoul Mining Co. in Korea. The addition at this point is considered essential in the treatment of the gold-copper ore, as the colloid slime becomes flocculated as soon as liberated, and allows the eucalyptus oil freer access to the mineral particles. To such an extent is this the case, that when ore is being milled containing appreciably coarse mineral particles, they are immediately floated out of the mill and freed from the risk of over-grinding. Prior to the addition of caustic soda at the ball-mill feed, the colloid slime appeared to coat and protect the sulphide mineral particles from oiling. The quantity added, as a 20% solution of NaHO, is 2 lb. per ton; and of eucalyptus oil 0.6 pound.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

COMPENSATION RESULTS.—TUOLUMNE COMPANY'S PROPERTIES.—
DAVIS-DALY AT DEPTH AND ZINC.—NEW COMPANY.

There are 1675 employees operating under the Workmen's Compensation Act. Practically all of the mining companies in the State are included in this total. Three plans were provided for carrying the risk. Some of the companies carried their own risk, and paid compensation direct to their injured men. For the 17 months that the law has been in effect their accident costs averaged less than 0.5% of the annual pay-roll. Under No. 2 plan, insurance companies paid the employee's claim, and collected premiums from the employers. The 13 different insurance companies had an accident cost of about 0.5% of the annual pay-roll. Under the third plan the State took the place of the insurance companies, and the cost was found to be about 0.5%. The costs prove conclusively that the premiums charged by insurance companies are too high. The premiums charged by the State amounted to less than 1%, which is perhaps the cheapest insurance protection in existence. During the 17 months there were 10,241 accidents reported, of which 197 were fatal. The few complaints made show that the law is giving complete satisfaction.

Tuolumne company's development on the 700-ft. level of the Butte Main Range mine continues satisfactory, and no doubt the property will develop into a good mine. The ore was found in a cross-cut that was driven south from the Sinbad shaft. The Spread Delight vein was cut, showing 4 ft. of 4% copper ore. Farther south, vein-material and altered granite were found, and then a body of ore 30 ft. wide was penetrated. The first 10 ft. averaged over 5% copper, and the remainder is said to be payable ore. Tuolumne controls the vein for a distance of 2400 ft. along the strike. For 1100 ft. the vein is in the Main Range. It crosses into the Colusa-Leonard to the west, which is also under option to the Tuolumne. A drift is being driven along the strike of the vein with encouraging results, and arrangements are being made to cross cut to the vein from the Colusa-Leonard shaft. The development will lend new impetus to the exploration that is being prosecuted in the eastern part of the district, and it is probable that several large mines will be developed in ground that has been repeatedly scorned by geologists. Of course, the present high price of copper could not be foreseen by geologists, and it is true that all these properties would be scrambling to make both ends meet if copper were selling for 16c, but it now seems certain that orebodies will be developed that can be worked with great profit after copper returns to its normal price.

It is rumored that the North Butte will sink a shaft in its ground east of the Main Range to explore veins at depth that have recently been exposed in an adit driven on the North western claim. The Tropic, Bullwhacker, and Butte Duluth, all in the eastern section, continue to yield good ore.

The Davis Daly is attracting much attention, and its shares have risen to several times their former price. Development on the 2500-ft. level is said to have disclosed a large body of high-grade copper ore. On the upper level, most ore was encountered, but because of extensive faulting none of the ore shoots were long enough to make the mine profitable. The company had to spend more for development to keep the mine in ore than the profit on the ore amounted to. The ore, found at 2500 ft. is said to be much better and wider than anything

found heretofore. New hoisting equipment is being installed, and a greatly increased production may be expected when it is ready. For some months past production has averaged 100 tons per day; the profit from this, even at the prevailing high price of copper, was not enough to meet expenses. With an increased production the cost will be materially lower, and a good profit should be made. Davis-Daly's position as a prospective producer of zinc has been greatly over-estimated. No ore has been developed in the Hibernia claim, and no commercial zinc ore has been developed in ground near it. The Hibernia has a good surface showing, but at best it is only a good prospect. In the Hesperus claim some narrow veins of high-grade zinc ore have been explored, and the ore will return a good profit if it is mined while the price of spelter is high. The tonnage developed, however, has been greatly exaggerated in the local papers, and has been favorably compared with the orebodies in the Rainbow lode that runs through the properties of W. A. Clark and the Butte & Superior. The veins in the Rainbow lode are from four to eight times as wide as the zinc-bearing veins in the Hesperus, and the shoots in the Rainbow are many times as long as any that have been discovered in the Hesperus.

A company has been incorporated to explore the Britannia and adjoining claims in the south-western part of the district. The Britannia is one of the old silver producers, and was worked for this metal to a depth of 700 ft. The veins that can be cross-cut from the old shaft are wide and long. The indications that point to commercial ore of the base metals at greater depth are as strongly developed here as at any point in the entire district. The management is capable and efficient. Of all the properties in Butte that are in the development stage this is the best gamble.

OUTMAN, ARIZONA

CONDITION OF THE UNITED EASTERN AND TOM REED MINES.

On about December 25, the exact time depending on the arrival of a consignment of cyanide, the new 200-ton mill of the United Eastern Mining Co. will commence, and shortly after should produce \$4000 to \$5000 of bullion per day. This plant will no sooner start than the Tom Reed Gold Mines Co. will commence the construction of a second unit of its mill, to increase the capacity from 150 to 300 tons per day. While this work is under way the Big Jim Mining Co. will have concluded its plans and will have let contracts for the machinery for a 400-ton cyanide mill which should be in operation within a year.

The United Eastern mill is a modern all-sliming plant employing the continuous counter-current system of decantation and agitation. The ore is crushed in solution in two 200-ton Marx ball-mills and ground to 200-mesh in three Allis-Chalmers 5 by 6-ft. pebble-mills with a capacity of 133 tons each with 85% through 200-mesh. The machinery is electrically driven. The gold of Outman mines is free and the ore requires fine grinding. The report of the Tom Reed company for the last fiscal year shows an extraction of 98.6%, crushing to 200-mesh. The crushing and grinding department of the United Eastern mill is designed to reduce 400 tons per day, but the capacity of the vats is limited to 200 tons. The mill is so constructed that the capacity can be increased at slight cost. Precipitation is by Merrill zinc-dust

system. The accompanying picture shows a compact arrangement of shaft equipment and mill.

The company recently sank a 3-compartment shaft to a depth of 725 ft., which has been connected with the vein, first opened through No. 1 shaft, on three levels. The shaft is timbered with 10 by 10-in. lumber, and arranged with ore-loading pockets on each level. The bins on each level have two compartments, one for each compartment of the shaft, and the pockets are so constructed that they contain an exact load for the skip. The cross-cuts are electric-lighted, and the shaft equipped with electric-flash signal system.

The development of the United Eastern mine from a rather doubtful prospect to a great gold mine, accomplished in two years' work, of which the greater part has been done within a year, is a splendid result. The company's property adjoins part of the three or four miles of land owned by the Tom Reed company. It was located by one Joe Perrizi, and as a result of his faith and perseverance he is now possessed of a fortune of \$250,000. In the autumn of 1913, J. L. McIver, who

opened on the 565 and 667-ft. levels, had exposed "sufficiently for sampling and assaying, 200,000 tons of ore assaying higher than \$20 per ton and having a gross value of \$5,000,000." Subsequent work has doubtless increased this quantity. Thus a mine was made, and incidentally several huge fortunes. At present market prices for the shares, Long and Melver are worth not less than \$750,000 each. W. K. Ridenour, who had faith in the mine when it was a prospect, bought treasury shares from Long and Melver at 25c. each. These are now worth about \$5 each. Wiseman, Mudd, Keith, and D. C. Jackling, who joined the first named trio, have profited also. Joe Perrizi sold 10,000 shares, according to rumor, bought an automobile and toured the country, and is now living luxuriously at San Diego.

No. 2 shaft was sunk about 300 ft. from the vein, which it should cut at 950 ft. This shaft is being sunk, and will be continued until the vein is intersected.

The Tom Reed company has opened a large vein in the south-east end of its ground and is rapidly developing this.

No. 2 SHAFT AND NEW MILL OF UNITED EASTERN AT OATMAN.

is known throughout Western camps as a champion double-hand driller, secured a bond on the Perrizi holdings, and with his partner, G. W. Long, organized the United Eastern Mining Co. Long and Melver had hard sledding, and for many months made slow progress in development, selling a few shares and working for wages in the Tom Reed mine to keep going. In December 1914, Frank A. Keith, Seeley W. Mudd, and Philip Wiseman, of Los Angeles, after an examination of the property by C. H. Palmer, Jr., contracted to purchase a large number of treasury shares for further development of the mine. A small gasoline hoist was installed and prospecting resumed under George W. Long. The shaft passed through the vein at 200 ft., where it was small, the best assays being \$8.78 per ton. At 300 ft. a cross-cut was driven to the vein which showed a width of 12 in., assaying \$14 to \$27; this was in October 1914. The important strike was in March 1915. At a depth of 465 ft. a cross-cut from the shaft exposed 25 ft. of ore that assayed \$22.93 per ton. Subsequently a drift driven along the foot-wall opened a shoot for 650 ft. in which some rich ore was found. At places on this and other levels the shoot is 40 ft. wide, an unbroken body of gold-bearing quartz excepting for an occasional horse of andesite. In May 1916, J. A. Burgess was appointed general superintendent. In June following he made a report stating that the mine, which had then been

The existence of a vein in this part, which is a mile from the main workings, has long been known, but it was not until the discovery on the Big Jim mine, which adjoins the Tom Reed on the east and south, that active development was undertaken. A shoot of good milling ore has since been proved for a length of 1100 ft. At a depth of 200 ft. on the Bald Eagle claim 33 ft. of quartz was exposed in a cross-cut, of which 26 ft. assayed \$9 to \$10 per ton. Farther south, 650 ft., the Aztec workings at 400 ft. cut 18 ft. of ore, of which 12 ft. on the hanging wall assayed \$8.50 and 6 feet on the foot-wall \$14.50. A drift was extended north-east 350 ft., and in several places face samples across the 6 ft. of drift assayed up to \$50 per ton. The entire 350 ft. is officially reported as milling ore of excellent grade. The shaft at 450 ft. is in 8 ft. of quartz worth \$13.88. Mine and mill costs are under \$6 per ton, so this grade of ore pays well. It is expected that the new unit of the mill, which will be equipped with Marcy ball-mills, etc., will lower the costs to \$5 or less.

Bulletin No. 43 of the University of Arizona at Tucson, by P. E. Joseph, deals with iron. Ten pages give the composition, characteristics, and tests for iron minerals, and three pages discuss the origin and uses. Some iron ores, such as the oxides and pyrites, occur in Arizona, and are used as fluxes, but no metal has ever been reported as made from the ores.

TORONTO, ONTARIO

FOREST FIRES AND PREVENTION.—RESEARCH COUNCIL.—PORCUPINE AND COBALT DEVELOPMENTS.

Important legislation embodying more effective means for the prevention of forest fires, which, with the opening of the wooded areas of Northern Ontario, are a continually increasing source of danger to the mining centres, is promised by the Provincial government. Last week a large and representative deputation waited on the Hon. G. Howard Ferguson, Minister of Lands, Forests, and Mines, to urge the need of stronger preventive measures and were assured that the Government was alive to the need for a thorough re-organization of the fire-prevention system to meet the new conditions. The first step taken was by establishing a separate branch of the Department with full control of the forestry and fire-prevention service, of which E. J. Zavitz has been appointed chief, with extensive power. The contemplated reforms, for which the sanction of the Legislature will be required, include the adoption of the permit system for the clearing of settlers' lands under which no burning of brush will be allowed, except under official direction, and the establishment of observation towers, trails, and a telephone system in connection with the fire-ranging service. It is also proposed to give the municipal councils more extended authority for fire prevention, and jurisdiction for some distance outside of town-limits.

The Canadian Government has appointed a number of scientists, engineers, and steel experts as an Honorary Advisory Council on Industrial and Scientific Research for the purpose of promoting the application of scientific methods to production and manufacture, utilizing waste products and discovering new processes. The Council consists of A. Stanley Mackenzie, president of Dalhousie college, Halifax, chairman; Frank D. Adams, and R. F. Ruttan, of McGill University, Montreal; J. C. McLennan and A. B. Macallum, University of Toronto; Walter C. Murray, president of Saskatchewan University; Robert Hobson, president of the Steel Company of Canada, Hamilton, Ontario; R. A. Ross, consulting electrical engineer, Montreal, and Tancrede Bienvenue, general manager of the Banque Provinciale, Montreal. The Council with others will carry on scientific and research work, and co-ordinate the work as far as possible to avoid overlapping, selecting the most practical and pressing problems and assigning them to research institutions for an early solution.

Porcupine had a three days' inspection last week from a large party embracing the members of the Standard Stock Exchange, Toronto, and a number of American capitalists from New York, Boston, and other points, as guests of the brokerage house of Mark Harris & Co. They visited the large mines, the principal object of the trip being the inspection of the Newray. It is anticipated that the result will be a considerable influx of American capital.

During November the production of bullion at the Dome mines was \$177,000, from the treatment of 37,900 tons of ore, valued at \$1.67 per ton. Operating costs of \$2.88 per ton were the highest for the year.

The 4-weekly statement of the Hollinger Consolidated for the period ended November 3 shows gross profits of \$241,591 from the treatment of 49,956 tons of ore, averaging \$8.62 per ton. The working cost was \$3.64 per ton. The deficit on the increased scale of dividends caused by the merger was \$238,118. The directors have ordered an issue of 120,000 shares of treasury stock, which will be offered to shareholders at \$6.50 per share, in the proportion of 1 share for every 40 old shares. The money to be raised will pay off the liability due to the shareholders of the Aene, Millerton and Canadian Mining & Finance Co. under the terms of the merger amounting to \$720,000, and leave a substantial sum towards the wiping out of the present deficit.

At the Lally, free gold is showing in the quartz vein, and the company is asking tenders for 1000 ft. of diamond-drilling

At the Davidson, Frank G. Stevens, the new managing engineer, has assumed control, and active development is meeting with good results. A raise from the 100-ft. level has exposed ore 8 ft. wide. Two small veins with free gold have been picked up 50 ft. in No. 2 shaft. D. R. Thomas has been appointed mine manager.

During November, the Schumacher produced \$18,295, at a cost of \$15,000. The new shaft has reached the 200-ft. level, where a station is being cut.

Sinking has been started at the Gold Reefs. The shaft now down 30 ft. will be sunk to the 100-ft. point at which cross-cuts will be driven to cut rich veins showing on the surface.

At the West Dome new equipment has been installed after considerable delay. The new 12-drill compressor is being operated by a 100-hp. motor. Forty-five men are employed.

An important strike has been made on the Aurum, formerly known as the Smith-Curry, in Munro Township, where a 4-ft. vein, showing free gold, has been opened.

Recent operations on the Ophir at Cobalt show encouraging results. In the cross-cut now at the 425-ft. level seven small veins were found within a distance of 20 ft. Three of them have united forming a strong vein 14 in. wide, and it is thought that they all converge into a considerable orebody. The important feature of this is that it shows an extension for about a half mile to the south of the silver-bearing belt on which the Beaver and Timiskaming are working.

The National Mines, operating the old King Edward under lease, is pursuing a deep-mining policy, and has sunk to the contact at 1170 ft., where a station has been cut and cross-cutting commenced.

WASHINGTON, D. C.

MINING LAW REVISION DOUBTFUL THIS SESSION.

No mining legislation is to be attempted in the present short session of Congress, at least this is the announcement of the House Committee on Mines and Mining, of which Representative Foster of Illinois is chairman. It is this committee that has set about the revision of the mining laws on its own responsibility, with the help of the mining authorities in Washington. Out of this has come the so-called Foster bill, which has been caustically criticized by the mining profession. This criticism has not been without force. It has served for one thing to make the Foster bill impossible, so that it is declared as dead, although really it may be said that it was written simply as a suggestion for the contemplated revision and codification of laws. Since then a concession has been made by the Committee, and that is to receive a bill which those mining men opposed to the Foster bill conceive ought to constitute the revision and which they are to draw up. Of course the House Committee refuses to commit itself with respect to this, but it will not be very welcome. All that members of the Committee will say is that it ought to serve as a good topic for discussion. It is expected that this bill will arrive during the present short session; but nothing is to be done regarding it in the way of substantial advance, for it is recognized that the session is too short for action in this Congress, even if an agreement respecting mining legislation could be reached. The Committee is as irreconcilably opposed to a separate and independent codification commission as ever. The chances for legislation in the next House can hardly be forecasted. For one thing, it is still in doubt which political party will control the next House, if any; there may have to be a coalition. So the complexion of the next committee on mines and mining of the House remains in doubt. One member will not be on it, and he is Delegate Wickersham of Alaska. He was defeated in re-election. Although without a vote in the Committee he had great influence over it, and has been the chief obstructionist to the revision and codification as desired by many in the mining profession, and recognized as being necessary.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ARIZONA

CHLORIDE. Roads in the vicinity of Chloride are in poor condition for teams, and all concerned are being asked to help in their improvement at an early date.

The district maintains its activity, especially in the copper zone. In the 170-ft. level of the Copper Age the shoot is 300 ft. long and 3 ft. wide, worth \$40 per ton in gold, silver, copper, and other metals. Foundations are being prepared for the concentrating mill.—The Diana claims have been bonded to G. Beveridge for \$20,000.—The Arizona-Chloride company has been completely financed.

JEROME. This centre has two large copper producers, the United Verde and the United Verde Extension. Eleven others have ore, namely, the Copper Chief, Pittsburg-Jerome, Arkansas & Arizona, Dundee, Verde Apex, United Verde Consolidated, Shea, Grand Island, and others.

MIAMI. At the Inspiration Consolidated it is proposed to enlarge the miners' change-house, the present one being overcrowded. Erection of a duplicate motor-generator set is under way at the mine power-house, to serve the hoists. Structural work on No. 19 and 20 units of the mill is finished. Foundations are to be prepared for the new flotation-plant blowing-engines. Ingersoll-Rand centrifugal and Root rotary blowers are used. Experiments are being made in leaching tailing.

The Miami Copper Co. filed a statement with the Court regarding its November results, as follows: pulp treated by flotation, 120,988 tons; copper in feed, 1.157%; concentrate produced, 1589 tons; copper in concentrate, 41.439%; copper in residue, 0.621%. The profit from this treatment was \$299,396. The feed had already been treated by water concentration.

OATMAN. A good development is reported from the Gold Road mine, details of which should be available soon.

CALIFORNIA

'Borax in 1915,' by Charles G. Yale, has just been issued by the U. S. Geological Survey. The output of crude borate materials in the United States was 67,003 tons, valued at \$1,677,099. In 1914 the yield was 62,400 tons and \$1,464,400. All the crude mineral is colemanite (calcium borate). The deposits are shown on the accompanying map. The production is derived entirely from California ore. The famous Lila C. mine of the Pacific Borax Co., in the mountains of the Death Valley region of Inyo county, after making a final small output early in 1915, was abandoned, and the company confined its efforts to the Biddy McCarthy and Widow mines, two new properties opened and made productive in 1915. A small 18-in. tramway connects with the narrow-gauge line to the main line of railroad. At this property more rotary furnaces are to be put in. At the Lang property of the Sterling Borax Co., in Los Angeles county, the calcining plant has been enlarged and new deposits have been opened. New rotary Wedge furnaces have also been put in. The Stauffer Chemical Co., of San Francisco, did not make any production at the Russell borate mines in Ventura county in 1915.

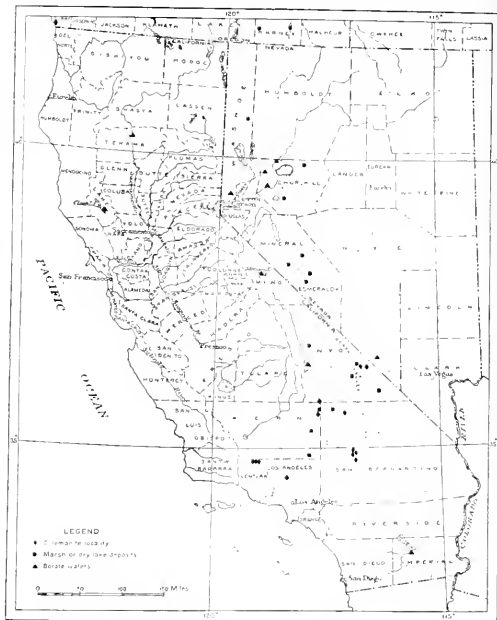

JACKSON. To cyanide tailing from the old Argonaut mill, Simmonds & Latham of Melones, Calaveras county, are to erect a plant costing \$15,000. There are 200,000 tons stored, which average from \$1.75 to \$2.50 per ton.

LEWISTON. The dredge on the Trinity river has been digging rich gravel, yielding much fine gold and nuggets. After

a 16-day run there was \$19,748 recovered. Chico people operate the Lewiston Dredging Company.

PLYMOUTH. According to W. J. Loring, the Plymouth Consolidated has produced nearly \$1,500,000 from 270,000 tons of ore in 27 months, of which \$460,000 was clear profit. The shaft is 2450 ft. deep, and is to be sunk 300 ft. lower. Reserves amount to 180,000 tons.

(Special Correspondence.)—Copper mining in Plumas county is exceptionally active. At Gullwing, the Walker mine, controlled by the International Smelting Co., is employing 75 men and is shipping concentrate. A 100-ton flotation plant is in operation and its capacity may be increased next summer. Small amounts of gold and silver occur in the ore.—A

MAP SHOWING BORAX DEPOSITS IN THE WESTERN UNITED STATES.

short distance from the Walker is the Bonita group, recently acquired by the Walker Bros. Consolidated Co. of Salt Lake City. Work has been going on for four years with encouraging ore exposures. A compressor and three machine-drills have been installed, and electric power will be extended to the mine as soon as the weather permits. Work started with H. L. Allread as superintendent. The Boca & Loyaltan railway, controlled by the Western Pacific, has arranged to extend its Grizzly Creek spur five miles, which will greatly facilitate ore shipments from this district.

Following a short-lived strike, influenced by I. W. W. agitators, the Engels Copper Co. has resumed operations near Taylorsville. The men demanded their wages be increased from \$4 to \$5 per shift, and for a time serious trouble was feared, as the strikers were promptly discharged and opera-

tions discontinued. Approximately 300 men are now at work, and a normal tonnage is being treated by the flotation plant. Driving of a main lower adit is progressing, and more equipment will be added to the plant shortly.

Many of the old gold producers of the county are active. At the Jamison mine, near Mohawk, 60 men are employed and the mill is running on good-grade ore.—Operations have been resumed at the Plumas Eureka, and an extensive campaign of development has been outlined. The property is a short distance from the Jamison.—A number of gold properties at Gold Lake, Beckwith, and other old centres are receiving attention.—Representatives of an Eastern syndicate have taken options on several copper properties at Greenville, and are preparing for thorough prospecting.

Quincy, December 19.

COLORADO

On January 9, 10, and 11 the Colorado Metal Mining Association meets at Denver. Among questions to be considered for a definite plan of action are the following: (1) Proposed repeal of the present law for the taxation of producing mines; (2) proposed change in laws regarding the Industrial Board and compensation insurance; (3) action of Association regarding regulation of smelters by Utility Commission; (4) proposed tariff laws affecting tungsten and other metals mined in this State; (5) co-operation of the State Association with similar organizations of other States for mutual benefit; (6) proposed changes in Federal mining laws; and (7) Government conservation policies and continued withdrawal from development of public lands.

At a meeting of a special committee of the tungsten producers of this State, appointed by the president, Bulkeley Wells, and composed of the following members: Harold Boericke, Primos N. & M. Co., Boulder; J. A. McKenna, Vasco M. Co., Boulder; Robert M. Keeney, Rare Metals Ore Co., Denver; J. G. Clark, Boulder Tungsten Production Co., Boulder; William Loach, Wolf Tongue M. Co., Boulder; Forbes Rickard, Ragged Top M. Co., Denver; Platt Rogers, Rogers Patent, Denver; Horace Holmes, Luckie 2 M. Co., Boulder; Geo. W. Teal, Tungsten Metals Co., Boulder; William Cowdry, Long Chance M. Co., Nederland; Nelson Franklin, Rare Metals Ore Co., Rollinsville; and H. N. Brown, Mojave Boulder Tungsten M. Co., Sugar Loaf; it was decided to call a meeting of the tungsten producers of the United States to convene during the annual meeting of the Association. This meeting is called for the purpose of a conference of the tungsten producers of the country to formulate a plan for concerted action in all matters affecting the industry, and especially to unite in an effort to secure as early as possible, favorable action on the part of the proposed tariff commission in behalf of a duty on tungsten ores and the products thereof.

LEADVILLE. The Derry Ranch dredge has been stopped for the winter, after working continuously for 8 months. Over 500,000 cu. yd. of gravel was dug, averaging at least 50c. per yard. In February the boat will be overhauled. R. E. Lafferty is manager.

At the Emmet shaft the Empire Zinc Co. is installing a G. E. 52-hp. hoist to replace an old steam engine, also a motor-driven compressor. Water in the Greenback shaft has been lowered to 1350 feet.

The Monarch company is to sink its shaft 100 or 150 ft. below the 750-ft. level.

At the Jamie Lee shaft of the I. S. S. R. & E. Co., a 105-hp. electric hoist has been put in place. Rubbish and mud in the shaft has hindered cutting out a pump station.

SHARON. According to the *Week's Mining* and *Trade* shipped approximately 60,000 tons of ore worth \$3,000,000 during 1916. In 1915 the quantity was only 500,000 tons. Snow prevented any shipments in January. Lead ore was mined near the Sunnyside, S. D. & G., Gold King, Doves, and other towns.

Tiger, St. Paul, Dives Leasing, Silver Ledge, and Silver Lake. Local custom mills were busy during the summer, and improved methods gave better recoveries. The coming year is expected to be a better one.

SNEFFELS. The report of the Atlas Mining & Milling Co. for the year ended June 30, 1916, contains the following information:

Underground development advanced 1681 ft. on the Klondyke vein, with favorable results. The amount of broken ore in reserve was increased by 9000 to 12,000 tons, worth \$75,000. An electric storage-battery loco replaced horses and mules in March, giving all-round better results. The mill treated 36,647 tons of ore averaging 0.0422 oz. gold, 9.19 oz. silver, and 35.2 lb. lead, worth \$6.77 per ton. Oil flotation gives 25% better recovery than by the tables; on gold this was 83.9%, on silver 87.9%, and on lead 90.4%. In June the average was 92.3%, and in November 93.6% silver and over 90% lead. Costs were as follows: Mining, \$1,8603; milling, 94.37c.; tramway, 10.27c.; maintenance, 23.49c.; development, 47.56c.; transport and marketing, \$1,2334; management, 19.37c.; taxes, 3.5c.; bond interest, 11c.; royalty, 12c.; and insurance 7.21c.; a total of \$5.3814 per ton. The year's revenue totaled \$212,156, of which \$17,265 was operating profit, less \$8437 for improvements.

IDAHO

ADAMS. Control of the Richmond Mining & Milling Co., which owns and is operating a group of six copper claims near here, has been secured by New York capitalists for a reported price of \$350,000, or on a basis of approximately \$500,000 for the entire property. The mine was reported on by B. N. Sharp, whose estimate of reserves was \$375,000 net. The average copper-content is 11%.

KELLOGG. According to S. A. McCoy, president of the Kellogg United Mines Co., a 100-ton mill and other equipment costing \$50,000 will be erected in the spring. The mine contains 40,000 tons of lead-zinc-silver ore, with recent developments indicating much more.

MURRAY. It is rumored here that the Guggenheim Exploration Co. has acquired a large tract of dredging ground along Prichard creek, and that prospecting will be continued next season.

PINE CREEK DISTRICT. The Douglas mine of the Anaconda company is shipping 20 tons daily of selected zinc-lead ore to Montana for electrolytic treatment, while preparations are under way to install new machinery.—The Highland-Surprise is the largest shipper in the district.

MICHIGAN

Houghton. Copper production of the Lake Superior region in 1916 will total 260,000,000 lb., a record. No Sunday work is done, this making the output 40,000,000 lb. less than it would have been, worth at 25c. per pound, \$10,000,000.

To July 1, 1917, the Calumet & Hecla and subsidiaries will pay 10% additional wages, while the present bonus of 25c. per day will be increased to 50c. The Mohawk and Wolverine companies will also pay the 50c. bonus.

The Quincy mine is producing 4200 tons of ore daily; one day's output was 1600 tons. This comes from three shafts.—Franklin is producing 1000 tons, to be 1300 tons by March.

After much delay, due to slow delivery of steel, the Champion has completed the frame of its re-grinding mill.

The threatened coal shortage in the Lake Superior region this winter will affect the smaller companies much worse than the others. The district, according to some of the largest dealers, is about 300,000 tons of coal short of actual needs. About the same quantity was shipped in as a year ago, but the mining companies were unable to get in the amount they ordered. The Calumet & Hecla company, alone, will be about 100,000 tons short. This company and its subsidiaries use 1,000,000 tons per annum. Plans for conservation of fuel

have been worked on by the company's officers for some months.

The Calumet & Hecla reports as follows for November, in pounds:

Mines	Month	11 months
Abmeek	2,157,959	21,820,622
Allonez	815,458	9,449,067
Calumet & Hecla	6,513,333	70,338,187
Centennial	155,505	2,174,350
Isle Royale	1,036,492	11,298,297
La Salle	135,220	1,211,141
Osceola	1,533,944	18,024,665
Superior	204,487	2,780,179
Tamarack	504,831	6,036,240
White Pine	314,534	3,969,142

MISSOURI

JOPLIN. Severe weather curtailed ore production last week. The coal situation—shortage and high price—is serious. Zinc ore declined \$5 per ton, while lead ore rose \$3. The output of the Missouri-Kansas-Oklahoma region was 9634 tons of blende, 342 tons of calamine, and 1241 tons of lead, averaging \$86, \$48, and \$90 per ton, respectively. The total value was \$965,004.

MONTANA

BUTTE. On the 1000-ft. level of the Butte & Zenith City mine the north cross-cut cut the hanging wall of the Paint vein. The casing has considerably altered granite mixed with it, and assays 1.45% copper and 3 oz. silver per ton. The south cross-cut and east drift is after the Economic vein.

The north cross-cut on the 1600-ft. level of the Butte & London has passed through 25 ft. of formation, 18 ft. assaying 1.2 to 8% zinc and several ounces of silver.

A gas pocket has been encountered during unwatering and repairing the Butte & Bacorn shaft, causing a slight explosion last week.

NEVADA

ELY. Effective from December 1 the Nevada Consolidated company is to increase wages 25c. per shift, to be paid while copper sales average between 27½ and 30c. per lb.; when the average is 30 to 32½c., another 25c. per shift will be paid to those employees receiving \$3 per day; while those getting under will receive a bonus of 20 cents.

LOVELOCK. In the Seven Troughs Coalition mine a winze is being sunk to 1900-ft. depth. This is to cut through the broken zone recently encountered. The mill continues to make a profit.

ROCHESTER. During 1916 the Rochester Mines Co. yielded approximately \$400,000, against \$334,157 in 1915, \$279,659 in 1914, and \$399,025 in 1913, a total of \$1,412,841.

TONOPAH. Last week the district produced 10,996 tons of ore valued at \$198,666. Some November outputs are as under:

	Tons	Oz. bullion	Profit
Belmont	12,027	230,058	\$121,265
Extension	9,019	145,973	52,670
Jim Butler	4,020	31,572
Tonopah Mining	8,555	167,315	50,550

VIRGINIA CITY. On December 21, water in the North End mines of the Comstock was down 38 ft. below the 2700-ft. level, which is good progress. The unwatering to 2900 ft. is being done through the Mexican-Ophir joint winze.

The Comstock Phoenix property, in a fissure running diagonal to the Comstock lode, has been acquired by Jesse Knight and others of Salt Lake City. The 650-ft. shaft is to be sunk to several times that depth.

NEW MEXICO

CUBA. In this district of north-central New Mexico, copper properties belonging to J. T. McLaughlin and others have re-

cently been sold, and ground will soon be broken there for a plant using modified pyrite smelting devised by Mr. Greenwald. This plant will utilize the sulphur deposits in the vicinity of Jemez springs, 30 miles away. The haul will probably be made by wagon, only a few tons of the low-grade sulphur-bearing travertine being required to add to the partly chalcocitic Cuba ores. These ores are of the bedded sandstone type, such as are found at Scholle, New Mexico.

(Special Correspondence.)—Three feet of \$12 ore has been opened in the south drift from shaft of the Eberle mine. The Oaks company will mill this as it does other ores at the Socorro mill.

At the Pacific mine, construction work is about completed for hoisting from the adit-level to the collar of the shaft. The ore will be dumped into chute to crusher, thence by belt-conveyor to bins at terminal of the aerial tramway to the Socorro mill. At present a large number of burros are employed moving an old ore-dump to the terminal station.

A new head-frame has been installed at the Trilby group, and sinking and driving will be started at once.

The Oaks Company has resumed sinking of the shaft on the Meridian claim. This is a fraction lying between the Top, on the east, one of the properties under operation by the Mogollon Mines Co., and the Confidence group on the west.

WINTER ALONG THE COMSTOCK, NEVADA.

which together have produced over \$5,000,000. Although surface rights are restricted, the fraction is considered valuable, as it embraces a constantly increasing length of this important vein as depth is gained.

Mogollon, December 12.

SILVER CITY. G. H. Utter has sold for \$200,000, on terms, to Los Angeles and New York capital the Jim Crow-Imperial claims in the Steeplecock district. The property contains gold and silver deposit. G. A. Whiteford of Los Angeles examined the mine.

OKLAHOMA

MIAMI. Drill-rigs are badly wanted in this district, which includes Cardin, Century, Picher, and Quapaw. One company, Church & Wright, wants 40 drills. For 3000-ft. contracts they will pay \$1.10 per foot. There are 200 drills working in the new district, and 500 around Miami. Drill-men are paid \$4.50 to \$5 per day.

OREGON

JACKSONVILLE. Little is published concerning mining in Jackson county. The reason why so little is being done is the short-sighted non-progressive crowd that 'guarded' the district and warned off would-be purchasers of properties, afraid that the mine-owners would not receive their dues. The county has had rich placer mines, and there are some that will still pay to work. There is also some likely looking ground in the ranges. A subscriber sends this news.

UTAH

ALTA. The daily output of the Alta district is irregular, due to the weather, but is from 150 to 250 tons.

The Emma Copper Co. expects to ship 30 tons of ore daily until the mine is further developed. A recent assay of 6 ft. of ore gives 175.6 oz. silver, 21.1% lead, and 0.91 oz. gold.

The Michigan-Utah is shipping 60 tons daily. A recent special carload was settled for, assaying 0.0325 oz. gold, 142.7 oz. silver, 11.9% lead, and 19.31% copper.

With 15 teams the South Hecla is able to move 50 to 75 tons of ore daily, and more regular shipments are expected.

GARFIELD. When the A. S. & R. smelter's additions are completed by about next November its capacity will be 6000 tons of ore per day, against over 2500 tons at present. There will be new furnaces, sulphuric acid plant, and electric apparatus; also a central bath-house for the 1500 employees. C. W. Whitely is manager.

MEXICO

Following is a translation of a decree by Carranza affecting the exportation of ores and metals from Mexico.

Considering that to aid in the re-construction of the country and to assist business back to normal, it is convenient to give necessary aid to home industries for the renewal of business that has been suspended and for the proper enlargement of those industries that have continued in operation; especially to the mining industry of such vital importance to the nation. It is well to give special facilities for the object indicated.

Therefore I have considered it advisable to make the following decree:

Art. 1. From December 10, 1916, to December 31, 1917, the export duties established by article 10 of the law of May 1, 1916, will be suspended.

Art. 2. During the time of suspension (December 10, '16, to December 31, '17) metals (for export) will pay the following rates: Gold and silver in bars, 5% of the assay-value; ores of gold and silver, 7% of the assay-value; copper in bars, 5% of value of metal; ores of copper, 6% of assay-value; other ores, 3% of value of metal.

Art. 3. To determine the value of the metals the Department of Hacienda will announce each month the prices that will apply for the following month, taking for a base, the prices given for metals in a separate circular by the Department of State.

Art. 4. If the value of copper goes below 20c. per pound in New York, the 5% for bars and the 6% for ores (and products) will be calculated on 95% of the New York quotation.

Art. 5. Exemption from export duties, established by Article 2 of addition G of the decree of May 1, 1916, will apply only in the following cases: Ores of copper less than 5% copper, ores of lead with less than 15% lead, ores of zinc containing less than 20% zinc.

Therefore, I send this to be printed, circulated, and complied with.

CONSTITUCION Y REFORMAS—Querétaro, Diciembre 8 de 1916.
V. CARRANZA.

Gold and silver bullion, and copper ore and concentrate, exported from Mexico to the United States, across the border, during 1916 totaled P24,827,169.

On December 19 the UTAH SECTION of the A. I. M. E. held its annual meeting and election at Salt Lake City. The following officers were elected for the ensuing year: C. W. Whitely, chairman; W. Wraith, vice-chairman; and Ernest Gayford, secretary-treasurer. Papers by J. M. Callow, entitled "Notes on Flotation, 1916," and by Irwin White, entitled "The Manufacture and Use of Sulphuric Acid," were presented. An address was also made by Major Westley King on "Military Conditions on the Mexican Border." The number in attendance, including the majority of the members of the local section and guests, was about one hundred.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

WILLIAM A. FARISH is at Salt Lake City.

HULKLEY WELLS is at the St. Francis hotel.

R. B. LAMB, of New York, is visiting California.

O. C. RALSTON spent Christmas at Colorado Springs.

LEON J. PEPPERBERG has returned from Salt Lake City.

T. WALTER BEAM is out of hospital, we are glad to state.

HORACE V. WINCHELL was recently in the Oatman district.

JOHN F. NEWSOM was at Salt Lake City just before Christmas.

IRA B. JORALEMON, of Bisbee, is spending the holidays at Berkeley.

FORBES RICKARD spent Christmas with his brother in Berkeley.

ETHELREIDE WALKER, of Boise, Idaho, spent Christmas in San Francisco.

J. E. JOHNSON, of New York, passed through San Francisco on his way to New York.

A. R. WEIGALL was at Kobe, Japan, during November, and has now returned to Korea.

SAMUEL WEIS, dredging engineer to the Lena Gold Mining Co., is purchasing machinery in San Francisco.

W. J. BLOCH has accepted the position of assistant superintendent of the Mile Wide Copper Co., near Tucson, Arizona.

EDWARD P. SCALON has been appointed superintendent of the Lincoln mine of the Inter-State Iron Co., at Virginia, Minnesota.

CHARLES B. CRONER is in charge of operations at the Bunker Hill mine, Inyo county, recently bonded to Los Angeles capitalists.

W. J. COX, manager of the Camp Bird, and HUGH ROSE, manager of the Santa Gertrudis, have been in London for the purpose of meeting their directors.

CHARLES T. KIRK, State geologist of New Mexico, has returned to Albuquerque from Oatman and the Big Bend country of northern Mohave county, Arizona.

FRANK LELAND has resigned as general manager of the Bala-kala and Trinity copper companies at Coram, Shasta county, to make his home in southern California.

JOHN ROBERTS MITCHELL, born at Perran Porth, Cornwall, in 1856, died at his home in Denver of heart disease on December 16. He spent some years in Ireland, where his father was manager for the Mining Company of Ireland; his first mining was in the Glendalough lead mines, county Wicklow; from there he went to Kimberley, accompanied by his brother James, and engaged in diamond-mining and in placer-work on the Vaal river. His next move was to America, visiting Leadville and the mining regions of New Mexico, settling down at Black Hawk, Colorado, in the early 'eighties; there he acquired a keen insight into the handling of low-grade gold mines. His next field of operation was the San Juan. Mr. Mitchell's superintendence of mines embraced California, Nevada, British Columbia, Mexico, and Alaska. For seven years he was superintendent of the Alaska Perseverance, now the Alaska Gold, and his work at that great mine received high commendation from the directors and stands as his best achievement. He was an able miner, a keen and progressive superintendent, a man of high character, and bore an unsullied reputation through the vicissitudes of 40 years in many lands. He is survived by a wife and son, a brother in Rhodesia, and by two sisters.

The annual meeting of the Colorado Metal Mining Association is to be held at Denver on January 9, 10, and 11. M. B. Tomblin is secretary.

THE METAL MARKET

METAL PRICES

San Francisco, December 26.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	35
Pig lead, cents per pound.....	8.00—9.00
Platinum, soft and hard metal, per ounce.....	\$85—91
Quicksilver, per flask of 75 lb.....	\$80
Spelter, cents per pound.....	14
Tin, cents per pound.....	43
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, December 26.

Antimony, 50% metal, per unit.....	\$1.00
Chrome, 40% and over, f.o.b. cars California, per ton.....	15.00
Magnesite, crude, per ton.....	6.50—9.00
Manganese, 50% (under 35% metal not desired).....	16.00
Tungsten, 60% WO ₃ , per unit.....	18.00—20.00

Tungsten is to be discussed by the Colorado Metal Mining Association at its annual meeting at Denver on January 9, 10, and 11.

The 'Manganese Number' of the 'Pahasapa Quarterly', published by the South Dakota School of Mines, will be found of value to producers.

New York, December 20.

Tungsten: Germany's peace overture was of great interest to the tungsten trade, in view of the fact that in times of peace she is the largest consumer of the ore. Brokers believe that a cessation of hostilities would for a time, at least, send prices upward. British and French buyers have been active in the past few days, taking ore for prompt delivery and over the first half of 1917, at prices ranging from \$16.50 to \$18 per unit, the latter for choice Argentine ore. A domestic consumer is in the market for a large quantity, and the market is stiff at \$17.50 to \$20, according to grade and position. Thirty of the largest consumers of tungsten in England have combined to build their own reduction works, but have been hampered by a shortage of ore.

Molybdenite: The supply appears to be inadequate to fill the available orders. Large orders for ferro-molybdenum are seeking placement. The quotation for molybdenite is \$1.80 to \$2 per pound.

Antimony: Ore is difficult to obtain, and up to \$1.70 per unit c.i.f., New York, has been offered.

EASTERN METAL MARKET

(By wire from New York.)

December 26.—Copper is dull and steadier; lead is quiet; spelter is steadier but quiet.

COPPER

Prices of electrolytic in New York, in cents per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date.	Week ending
Dec. 12.....	\$6.00
Nov. 28.....	\$7.00
Dec. 5.....	\$8.00

Tin is steady at 41 cents.

ANTIMONY

Quotations at New York show considerable irregularity, ranging all the way from 13 75 to 14.50c, duty paid, for Asiatic grades. There is not enough business to actually test the market.

ALUMINUM

The quotation for No. 1 virgin aluminum, 98 to 99 1/2 pure, is unchanged at 63 to 65c. per pound.

Eastern Metal Market

New York, December 20.

Despite the unquestioned sold-up state of producers, who have but little copper to sell in the first half of 1917, the peace talk has unsettled the market and brought out offerings from second-hands. While a good quantity of metal was undoubtedly in speculative hands, they are not the only would-be sellers, for at least a few consumers have placed copper in the hands of brokers. The great quantity sold, however, will undoubtedly act as a bulwark against any radical decline in prices.

Zinc has declined steadily in a quiet market.

Lead prices have dropped sharply, and all interests are now at the same level—7.50c., New York. Where there was a seeming shortage of lead, second-hands are now pressing the metal for sale.

Antimony and aluminum are quiet. While there is a wide divergence of opinion as to what Germany's peace proposal will amount to, it is notable that many factors of the metal trade who have close connections abroad believe that peace is not far off. They base their opinion on the attitude of the Germans themselves. In the past week, for instance, a German banker representing German financial interests in New York has expressed a belief that peace is near. The two largest German trans-Atlantic steamship lines have sent out letters inviting communications concerning freight space and rates "when the War is ended," and letters from abroad show a conservative strain.

The iron and steel market was rendered distinctly quiet when the peace announcement was received, but the quiet was only temporary, and conditions are now much the same as they were before, so far as finished steel is concerned. Pig iron is not so active, but prices have not suffered. The interruption exercised a healthful effect on business, inasmuch as from now on, buyers will not lose sight of the fact that the War must end sooner or later, and will govern themselves accordingly. France and Italy have placed additional orders for steel in the past week. It also may be noted that should a condition arise which would call for the cancellation of war steel, the same tonnage would be diverted to plates, shapes, and bars, for which peace would bring a great demand. Some of the war contracts are stated to have such a proviso.

COPPER

Although the producers assert that their prices have not been changed since Germany's suggestion that she would welcome peace under satisfactory terms, second-hands, including consumers, have offered copper at substantial concessions. It is predicted that the business of the next few months will be done by second-hands, this view being based, of course, on the sold-up state of the producers. As for activity, none of moment is expected this year, or early in 1917. Prices are too high to start a movement of noteworthy proportions, while the sellers are too well filled with orders to let quotations drop far. In far-off positions considerable short selling is reported, indicating that speculators are willing to gamble that prices will be lower in the last half of the year. It is reliably stated that a large mill became so disturbed over the peace talk that it offered 1,000,000 lb. of prime Lake copper last week at 30c. per pound. It cannot be learned that the copper was taken. There has been some business in the past week, mostly for nearby delivery, although August and September was sought also. Generally, the market has been quiet both sellers and consumers being inclined to simply watch developments. It is curious that, whereas prompt copper was so scarce prior to the news from Germany, it is now quite plentiful, a fact only to be accounted for by offerings on the part of

consumers and speculators. January electrolytic and Lake were offered yesterday at 35.50c., and first quarter at 31.50 to 32c., with the latter figure more generally prevailing. Spot was nominally around 34c. While awaiting Lloyd-George's reply to Germany on the 19th, the market was in a nervous state, with thought concentrated on what an early ending of the War would mean. One reassuring theory was that Great Britain would take the 200,000 tons it purchased for delivery over the first half of 1917, but that the metal would be used for industrial instead of war purposes. She now has a firm grasp on the copper within her boundaries and is regulating both the price and consumption, none being used for any purpose except by express permission of the Government. The London quotation for spot electrolytic yesterday was down to £161 against £168 a week previous. Exports from the 1st to 20th total 14,040 tons. It is yet too early to tell just what the copper market is going to do, but a period of dullness is indicated, with second-hands making the sales. They usually will make concessions to get business. Brass and copper products are as strong as ever. Since the beginning of the peace talk one or two Dutch concerns have cabled, asking that shipments to them be hurried.

ZINC

The decline in spelter has continued, and December delivery was sold yesterday at 10c., St. Louis, by second-hands. They also disposed of second quarter at 9.25 to 9.50c., St. Louis. First quarter was quoted yesterday around 9.75 to 10c., St. Louis, the new York quotation ranging about 25 points higher for each position. The situation is unsettled, with little business to be reported. Representatives of some of the producers are quoting above what appears to be the market, insisting that they believe fundamental conditions to be sound, and that January will see higher prices. Of course, those who take this stand are undoubtedly well filled with orders for the next few months. The London spot quotation yesterday, the 19th, was £54 5s., compared with £57 a week previous. Exports in 20 days total 2787 tons, a poorer showing than has been usual of late. Sheet zinc is unchanged at 21c. per pound, f.o.b. smelter, 87 off for carloads.

LEAD

This metal has been acting more or less in company with copper, in that prices have declined and stocks appeared which were not supposed to be in existence. In the past few days the market has entirely reversed itself. On December 11, independent producers were asking 8c., New York, whereas yesterday they quoted 7.50c., New York, and about 7.40c., St. Louis. In the course of the decline second-hand lots were freely offered, showing that a good deal of metal has been held for speculation. The London quotation was unchanged yesterday, the 19th, at £30 10s. Exports from December 1 to 20 were small, amounting to only 122 tons.

TIN

On the 18th about 200 tons changed hands, and yesterday, the 19th, 100 tons was taken, otherwise the market has been quiet since the last report. The buying referred to was confined to a few concerns, and is believed to have been done for the purpose of covering contracts against which tin had failed to arrive. The quotation for spot Straits has weakened during the dullness, and yesterday 42.37½c. was quoted. Should definite steps toward peace be taken, it is thought that the tin market would be benefited, inasmuch as it would mean the earlier restoration of a wider market. Plenty of tin is available. Arrivals in December, including the 19th, amounted to 1070 tons. There are 6393 tons afloat.

Mining Decisions

MINING CLAIMS—TAXATION

The Idaho Statute requiring assessors to assess mining claims by taking the Government price per acre for mineral lands as a basis for valuing the surface, adding the cash value of improvements, and then adding the net output for the preceding year, was held constitutional.

Hanley v. Federal Mining & Smelting Co. (Idaho), 235 Federal, 769. July 22, 1916.

OIL LEASE—EXTENSION VALID

A grantor, having granted an extension of the time a well should be drilled under an oil lease in consideration of quarterly payments, sought to terminate the extension within the term thereof by refusing to accept the quarterly payments when tendered. Held, the extension was binding upon the lessor.

Leonard v. Busch-Everett Co. (Louisiana), 72 Southern, 749. October 16, 1916.

OIL LEASE—FAILURE TO DRILL OFF-SET WELLS

Under an ordinary oil and gas lease where delay rentals were provided for, paid and accepted, there was no implied covenant by the lessee to drill off-set wells to prevent drainage through wells driven on adjacent land, and his failure to do so during the period in which he was paying and the lessor was accepting such rentals does not make him liable for damages on account of such drainage.

Stanley v. United Fuel Gas Co. (West Virginia), 90 Southeastern, 344. October 10, 1916.

ASSESSMENT WORK PREVENTED BY FORCE

Where defendant prevented plaintiff's predecessor in title from performing the assessment work on a mine for a year, driving away laborers and threatening them, defendant, whose location overlapped that of plaintiff cannot base any rights on the failure of plaintiff and his predecessor to perform the assessment work, particularly where there was no showing that there was any part of plaintiff's claim outside the overlap on which assessment work might have been beneficially performed.

Ames v. Sullivan (Alaska), 235 Federal, 880. September 5, 1916.

OIL AND GAS LEASE—UNCONSCIONABLE FORFEITURE ENJOINED

Where an oil and gas lease provided for forfeiture for non-payment of rent, and the lessee after paying rent promptly for 13 years, in the 14th year sent his check so that it reached the lessor the day after it was due and before a forfeiture had been declared, a forfeiture would be unconscionable and the lessor will be enjoined from enforcing it. An oil and gas lease is not a mere license, but creates a corporeal interest in the land which does not divest except through a lawfully declared forfeiture.

McKean Natural Gas Co. v. Wolcott (Pennsylvania), 98 Atlantic, 955. July 1, 1916.

OIL AND GAS LEASE—EXTENSION—DEATH OF GRANTOR

A grantor of an oil and gas lease died, and his widow, being entitled to one-half of his estate and the usufructuary rights to the other half, granted extensions from time to time for additional considerations paid by the lessee. She died before the last extension had expired, and her daughters, being joint heirs to her estate, attempted to have the lease declared forfeited because no wells had been driven within the period

originally contemplated, alleging that their mother's last extension was terminated by her death, because she had had only the usufructuary use of half of the land. Held, that as the daughter's based their title solely on their unconditional succession to their mother's estate they could not avoid the lease.

Cochran v. Gulf Refining Co. of Louisiana (Louisiana), 72 Southern, 718. October 16, 1916.

OIL-LAND WITHDRAWAL—SUBSEQUENT CLAIM VOID

Locators who had expended some \$20,000 in a fruitless attempt to make a discovery of oil, and discontinued work on their claims except for the employment of a watchman, prior to the issuance of the Taft withdrawal order of 1909, cannot vest any title under such attempted location in an assignee who comes in several months after said withdrawal order took effect and actually develops oil. Such an assignee is a mere trespasser on the domain of the United States, and will be enjoined from further work and a receiver appointed to take charge of further operations.

United States v. McCutchen et al. (California), 234 Federal, 702. July 12, 1915.

QUARRY LEASE—IMPLIED COVENANT

A quarry lease for "as long as the property is suitable for quarrying purposes," and providing for royalties per cubic yard of stone excavated, by implication obligates the lessee to work the quarry or sustain the burden of proof in a suit for royalties that the quarry cannot be profitably worked. The mere fact that it would require larger machinery than that which had been installed by a previous lessee does not excuse his performance. If the rock is shown to be there, he will be held to his implied covenant to excavate it or to pay damages for failure so to do.

Stoddard v. Illinois Improvement & Ballast Co. (Illinois), 113 Northeastern, 913. October 24, 1916.

MINING CONTRACT—CONSTRUCTION

A mining contract required the purchaser to pay a percentage of the net profits thereunder, after deducting from gross receipts the actual expense of labor including wages, team-hire, and board. Held, that such language did not include permission to deduct the cost of materials and supplies such as shovels, picks, and lumber. Nor, if the purchaser departed from the methods of mining originally contemplated by the agreement for the purpose of employing the more economical hydraulic method, was he entitled to charge more than the stipulated price for water, although the high-pressure water, necessary for hydraulic mining, might as a matter of fact cost more.

Blanc v. Pioneer Mining Co. (Washington), 159 Pacific, 1077. September 15, 1916.

IRON-MINING LEASE—CLAUSE CONSTRUED

An iron-mining lease, providing for minimum ground rents in substantial amounts, contained a clause to the effect that the lessee should "work the mine or mines now or hereafter discovered on said lands in a good workman-like manner during the existence of the lease" and that forfeiture should be had for failure of the lessee to "work such mine in a good workman-like manner or fail to pay the ground rent when due." For 10 years lessees paid and lessors accepted the minimum ground rent, but no work other than prospecting was done. Held, on suit by lessor for forfeiture that the above clauses only required "good and workman-like work" if any work was undertaken, but did not obligate the lessee to keep up mining operations so long as he paid his ground rent.

Niles Land Co. v. Chenung Iron Co. (Minnesota), 234 Federal, 294. April 28, 1916.

Book Reviews

MINING AND MINE VENTILATION. By Joseph J. Walsh. P. 180. Ill. and index. D. Van Nostrand Co., 25 Park Place, New York, 1915. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$2.

The author of this book had a large practical experience in matters of mine ventilation in a region, Wilkes-Barre, Pennsylvania, where this is a positive necessity. Here he has written a treatise both interesting and valuable. There is given a method for determining the size of fan or blower required to ventilate a mine under given conditions. There is also a chapter on mine fires which will interest all mining men, and the chapter on mine lamps is also of value and full of common-sense suggestions.

FLOW OF WATER IN PIPES. By George T. Prince. P. 149. Charts and tables. D. Van Nostrand Co., New York, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, \$2.

The notes and tabulated data in this book refer to the flow of water under pressure through clean, closed pipes, collected by the author while chief engineer for a water-supply company at Denver, Colorado. In that city there is over 100 miles of continuous wood-stave pipe from 30 to 48 in. diam. The importance of pipe-design was investigated, and flow-data were compared with accepted formulae, five of which were selected by means of which 123 pages of tabulated values were computed. Therein is calculated the fall, velocity, and discharge from pipe 4 to 120 in. diam. Thirteen pages discuss formulae, and nine plotting flow-data by means of logarithms. Hydraulic engineers should find this little book of service.

TREATISE ON HYDRAULICS. By Mansfield Merriman. Tenth edition. P. 556. Ill., index. John Wiley & Sons, Inc., New York. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.

In the latest edition of this standard work, a considerable part has been revised or re-written and considerable new matter added. The more important additions include a complete table of values for n in Kutter's formula, based upon Horton's recent experiments and a discussion of the newer types of hydraulic turbines. The chapter headings are Fundamental Data, Hydrostatics, Theoretical Hydraulics, Instruments and Observations, Flow through Orifices, over Weirs, through Tubes, through Pipes, in Conduits, Flow of Rivers, Water Supply and Water Power, Dynamic Pressure of Water, Water-Wheels, Turbines, Naval Hydromechanics, and Pumps and Pumping. The hydraulic tables are placed in the text next to the explanation of their use, but a special index of the tables facilitates reference.

THE FUNDAMENTAL PRINCIPLES OF PETROLOGY. By Albert Johannsen, translation from the German work by Dr. Ernst Weinschenk. P. 211. Ill., index. McGraw-Hill Book Co., Inc., New York, 1916. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$2.50.

This work, recently translated from the original German, will prove of great value to the students of petrology. Its title is, perhaps, somewhat misleading, as it is in no sense a treatise on microscope petrography, but a clear and comprehensive dissertation on the character of rocks—what they are, and how they came to be as they are found. It deals with the solidified crust of the earth and the rocks that comprise it, and particularly with the alterations to which rocks have been subjected and the causes therefor: the composition of igneous rocks; rock-weathering processes and their results; the nature of sediments and the metamorphism of sedimentary and other rocks, and post-volcanic processes. An understanding of these

subjects cannot fail to be of value to any student who desires to become proficient in the study of rocks, either microscopically or otherwise. The book is profusely illustrated.

LABORATORY MANUAL OF BITUMINOUS MATERIALS. By Prevost Hubbard. P. 153. Ill. John Wiley & Sons, Inc., New York. For sale by MINING AND SCIENTIFIC PRESS. Price \$1.50.

The title of the book states that it is for the use of students in highway engineering. This doubtless includes the many engineers now engaged in highway construction who completed their technical training before highway engineering became recognized as a special subject, and who, as well as the college student, will find the present volume of value. Part I gives a general discussion of bituminous materials. Part II describes in detail the various tests and the different methods used for making these tests. Part III gives the characteristics of the more important bituminous materials. A number of blank pages for notes are included with the text.

CONTRACTS, SPECIFICATIONS, AND ENGINEERING RELATIONS. By Daniel W. Mead. P. 518. Ill., index. McGraw-Hill Book Co., New York. For sale by MINING AND SCIENTIFIC PRESS. Price, \$3.

The divisions of this book that treat of contracts and specifications are similar in character to several other treatises on these subjects that have appeared during the past few years, although the treatment is perhaps more complete in the present volume. The division dealing with engineering relations, which includes presumably the chapters on The Engineer and His Education; Success in the Engineering Profession; The Engineer at Work; Personal and Ethical Relations; The Use of English; Letters and Reports; Origin, Nature, and Development of Law; Some Legal Relations of Technical Men; and Legal Rights and Responsibilities, is largely devoted to matters that have never been discussed so thoroughly before. It is also true that discussion of a number of subjects that is usually found scattered among a number of volumes is here grouped so that the relation between them is clearly shown. It has frequently been pointed out that the work of the true engineer deals with men as much as with materials and machines. We know of no book better suited to guide the young engineer in his relations with men than the present volume. However, the book is of value to the experienced member of the profession as well as to the student and young engineer. The older engineer will probably find a good deal that he did not know before, besides being able to use the volume as a reference book to make sure that he has omitted nothing in the preparation of an important set of specifications.

Following the chapters already mentioned, there are several that comprise a brief but complete discussion of the law of contracts as applied to engineering and construction matters, not befogged by unnecessary legal terms. The sections dealing with specifications discuss the general principles underlying specification writing and then proceed to the consideration of specifications for particular kinds of work and materials. Here also the emphasis is laid upon the objects to be attained by each clause in the specifications, rather than upon the wording of particular sections. In fact, special attention is paid to the danger of copying specifications used on some other work without making sure that each clause is applicable to the work in hand. There are four appendices. The first contains outlines of specifications for several different kinds of construction. The second contains a sample contract and specifications for a complete structure, in this case, a concrete reservoir and suction-well. The third contains a number of examples of drawings that may be used in connection with specification writing. The fourth is a classified bibliography, whose completeness may be judged from the fact that it comprises 50 pages.
